PREFACE

The American Management Association has felt for some time the need for bringing together in convenient handbook form not only a digest of the best of its own publications, fully revised, but also contributions covering the field of modern management methods. Consequently, arrangements were made with the publishers for the preparation and publication of this Handbook. It is hoped that in this form executives of all grades and types, and students of management generally, will find a reasonably complete picture of modern management methods.

One of the most pressing problems of management today grows out of extreme specialization in executive duties, which, during the last ten or fifteen years, has somewhat destroyed the opportunity for that well-rounded experience which prepares an executive for promotion into general managerial positions.

That this tendency has gone too far is indicated by the opinion often expressed that it is extremely difficult to find men for promotion into positions of major managerial responsibility. Another complaint frequently voiced is that many executives concerned primarily with finance know altogether too little about production or marketing and that similarly marketing and production executives often know altogether too little about the other major aspects of the business.

It is equally true that specialists within these major functional divisions of a business often know too little about special sectors of their particular field, such as production management, marketing, or finance.

The net result is an extremely difficult problem of coordinating different activities with a particular function, such as finance, production, or marketing, and sometimes a still greater problem of coordinating the activities and points of view of executives having major functional activities.

There are several ways of meeting this difficulty, including, among others, organized managerial training within a corporation, systematic use of the opportunities offered by universities through extension courses and night-school courses, planned attendance at conventions and conferences of management and other associations, and the reading of current magazines.

It is a fundamental of sound educational procedure, however, that what is learned should be learned, so far as possible, at the time when the need arises and at a time when what is learned may be put into practice through improved skill.

This "Handbook of Business Administration" will, to a considerable extent, meet this educational need by providing in a form convenient for study the fundamentals and the procedures of managerial policy and technique which may be put to use by business executives as problems arise and as the business process changes.

It is our hope, too, that this "Handbook of Business Administration" will find its way into the hands of many business executives who have heretofore not been associated with the management movement either in America or abroad.

Essentially the Handbook has been prepared to meet the needs of the following groups:

1. Executives of general managerial rank who want a source of information which will help them to determine the relative efficiency of their own functional departments. A president or a general manager, for instance, by reviewing the section on Production or Office Management or Personnel can gain a well-balanced picture of tested practice in those fields and is thus able to form an idea of the extent to which his own similar department has succeeded in keeping pace with up-to-date practice.

2. Those major functional executives who are similarly anxious to maintain a perspective on progress in various sectors of their special fields. The vice president in charge of production, for instance, will find in the Production Section a means of judging the relative efficiency of a production control department or the inspection department and of reappraising his plan of incentives for manual workers.

3. Those business executives of more or less specialized responsibilities who desire a bird's-eye view of sound accepted practice in their own particular field of activities, such as marketing, production, finance, and office management. The time study engineer can do his work best if he is thoroughly familiar with the whole production process. One specialized activity cannot live unto itself. Time study work, for instance, has a close relationship to design, to personnel, to production control, to quality control, and to many other aspects of production.

4. Those specialized executives who need and wish to have at hand a source of information and the point of view of executives in specialties other than their own, particularly as a means of developing their own capacities in anticipation of promotion and partly so as to permit them to conduct their own specialized activities with a greater understanding of their relationship to other activities within the organization.

The contributors to the various sections of the Handbook have been carefully chosen as leaders in their respective fields. Their contributions represent what is believed to be among the best in modern managerial policies and procedures. The Production Section, for instance, of itself is a handbook, to a considerable extent, for production executives ranging from vice president in charge of manufacturing to the supervisor of specialized activities or departments.

W. J. DONALD,
Editor-in-Chief.

NEW YORK,
June, 1931.

ACKNOWLEDGMENTS

The editors have made every effort to secure the different contributions from those most eminently qualified in the various fields, but neither they nor the American Management Association assume specific responsibility for statements of opinion made by the contributors. The editors recognize, too, that doubtless there are many equally competent contributors on the various subjects embraced in the Handbook. Nevertheless, every effort has been made to secure a contribution in each case from one of the outstanding men in the field.

The outline of the contents for the Handbook and, to a large extent, the choice of contributors have been made by the editors with the advice and cooperation of an advisory committee and sub-committees. Grateful acknowledgment is made to the following:

Paul A. Anderson, Treasurer and Manager, New England Laundries, Inc.

W. M. Beers, General Auditor and General Methods Accountant, Western Electric Company.

H. B. Bergen, Director of Industrial Relations, The Procter & Gamble Company.

P. D. Betterley, Assistant Treasurer, Graton & Knight Company.

Glenn A. Bowers, Director of Study of Business Conferences, The Inquiry.

C. R. Cary, Vice President in Charge of Sales, Leeds & Northrup Company.

C. S. Ching, Director of Industrial and Public Relations, United States Rubber Company.

Harold V. Coes, Manager, Industrial Department, Ford, Bacon & Davis, Inc.

W. F. Coleman, Vice President in Charge of Manufacturing, W. A. Jones Foundry and Machine Company.

Edward S. Cowdrick.

H. G. Crockett, Partner, Scovell Wellington & Company.

E. P. Curtis, General Sales Manager, Motion Picture Film Division, Eastman Kodak Company.

P. L. Dildine, Manager, Factory Standards, The B. F. Goodrich Company.

C. R. Dooley, Personnel Manager, Standard Oil Company of New York.

Ernest G. Draper, Vice President and General Manager, The Hills Brothers Company.

Harvey G. Ellerd, Personnel Department, Armour and Company.

Allan Everett, Manager, Planning Department, Henry L. Doherty & Company.

Dwight T. Farnham, Manager, Industrial Department, Peat, Marwick, Mitchell & Company.

William B. Ferguson, Consulting Industrial Engineer.

Norman C. Firth, Managing Editor, *System*.

H. A. Fountain, Vice President, The First National Company.

H. B. Gilmore, Secretary, Western Electric Company, Inc.

Lillian M. Gilbreth, President, Gilbreth, Inc.

William J. Graham, Vice President, The Equitable Life Assurance Society of the United States.

E. O. Griffenhagen, Griffenhagen & Associates, Ltd.

W. A. Griffin, Assistant Vice President, American Telephone and Telegraph Company.

Dr. C. Frederick Hansen, Director of Standards, W. T. Grant Company.

Marshall L. Havey, General Sales Manager, New Jersey Zinc Company.

Walter C. Hill, Vice President, Retail Credit Company, Inc.

Gorton James, Vice President, The Thompson & Lichtner Company, Inc.

E. C. Johnson, President and General Manager, H. A. Johnson Company.

Mark M. Jones, Consulting Economist.

Thomas R. Jones, Vice President and General Manager, Harris-Seybold-Potter Company.

J. P. Jordan, Partner, Stevenson, Jordan & Harrison.

Hugh B. Killough, Barrington Associates, Inc.

W. S. Landes, President, Celluloid Corporation.

Godfrey Lebharr, Editor, *Chain Store Age*.

Sam A. Lewisohn, Vice President and Treasurer, Miami Copper Company.

Cooke Lewis, Vice President, Liberty Mutual Insurance Company.

E. E. Lincoln, Economist, International Telephone and Telegraph Corporation.

Eleanor H. Little, Assistant Supervisor, Industrial Relations, The United States Rubber Company.

Charles W. Lytle, Director of Industrial Cooperation, New York University.

A. L. MacDonald, Chief Accountant, The Bank of Nova Scotia.

John H. MacDonald, Auditor and Office Manager, Keller Mechanical Engineering Corporation.

J. E. MacPherson, Vice President, The Bell Telephone Company of Canada.

George D. Olds, Jr., General Sales Manager, The Hills Brothers Company.

John C. Orcutt, Vice President, Irving Trust Company.

Hadar Ortman, Director of Operations and Finance, Meredith Publishing Company.

Raymond S. Perry, Vice President, Ingersoll Milling Machine Company.

John O. Platt, Vice President, Insurance Company of North America.

S. R. Rectanus, Vice President, The American Rolling Machine Company.

O. D. Reich, Vice President, Dexter Folder Company.

I. O. Royse, Manager, Office Production, Ralston Purina Company.

Merrill B. Sands, Vice President, Dictaphone Corporation.

Mary E. Scott, Personnel Assistant, Standard Oil Company of New Jersey.

C. A. Scully, Vice President, Bank of Manhattan Trust Company.

Orrin G. Sherman, Assistant Secretary, McGraw-Hill Publishing Company.

E. O. Shreve, Assistant Vice President, General Electric Company.

F. A. Silcox, Director, Industrial Relations, New York Employing Printers Association.

H. J. Taylor, Vice President, Jewel Tea Co., Inc.

W. S. Vivian, Vice President in Charge of Public Relations, Middle West Utilities Company.

Earl Whitehorne, Assistant Vice President, McGraw-Hill Publishing Company, Inc.

Irwin D. Wolf, Secretary, Kaufmann Department Stores, Inc.

C. K. Woodbridge, Vice President, Remington-Rand, Inc.

Arthur H. Young, Secretary, Industrial Relations Counselors, Inc.

Benjamin E. Young, Comptroller, Commerce Trust Company.

We wish also to acknowledge the cooperation of various publishers for permission to use material heretofore published, as follows:

Harper & Brothers, The Ronald Press Company, The American Society of Mechanical Engineers, The Architectural Forum, McGraw-Hill Publishing Company, and the McGraw-Hill Book Company, Inc.

MARKETING

CHAPTER I

MARKET RESEARCH AND ANALYSIS. BY WILLIAM J. REILLY	3
Information that Helps the Marketing Manager.	
Diagnosing the Market Situation.	
Studying the Industry.	
Sources of Industrial Information.	
Gathering and Interpreting Industrial Information.	
Illustration: Study of the Baking Industry.	
Studying from the Inside Out.	
Getting Unrecorded Specifics from the Organization.	
Analyzing Company Records.	
Check List of Factors Affecting Sales and Consumption of a Product.	
Studying from the Outside In: The Consumer.	
Kinds of Information to Be Secured from Consumer.	
Freezing the Results of a Survey in Advance.	
Representative Information from Interviews.	
Guarding against Personal Bias of Investigators.	
The Difference between Answers and Facts.	
From the Outside In: The Retailer.	
Kinds of Information to Be Secured from Retailer.	
Interviewing the Retailer.	

From the Outside In: The Jobber.	
Kinds of Information to Be Secured from Jobber.	
Means of Gathering Market Information.	
Difficulties in Use of Mail Questionnaire.	
Keeping in Continual Touch with Major Factors.	
Potential Market Factor.	
Price Factor.	
Style Factor.	
The Changing Consumer.	
System of Sales Territories.	

CHAPTER II

ADVERTISING. BY WILLIAM J. REILLY 37

The Total Situation Approach to Advertising.	
Effects of Volume Increases.	
Seeking Profitable Increase in Volume.	
Recording Effects of Volume on Costs and Profits.	
John A. Manufacturer's Production Costs.	
John A's Marketing Costs.	
Rising Marketing Costs and Declining Profits.	
Study of Costs from Inside Out.	
Study of Causes from Outside In.	
Considering Various Marketing Instruments.	
The Product Itself.	
Availability of the Product.	
Price of the Product.	
Advertising and Personal Selling.	
Defining the Advertising Job.	
Study of the Situation.	
The Advertising Objectives.	
Selection of Media.	
Measurement of Advertising Effect.	
Possibility of Measurement.	
House to House Advertising.	
Selling vs. Sampling.	
Cost of Sampling.	
Other Methods.	
Special Dealer Advertising.	
Window Displays.	
Effects of Mass Media.	
Early Attempts to Measure Effects.	

Costs vs. Results.	
Limitations of Inquiries as a Measure.	
Need for Continuing Experiments.	

CHAPTER III

MERCHANDISING, ADAPTING THE PRODUCT TO THE MARKET. BY H. A. RICHMOND	68
---	----

Merchandising Defined.	
Objectives in Merchandising.	
Putting Sales Interest into the Product.	
Product Improvement.	
Developing New Uses.	
Changing Style or Design.	
Introducing Color.	
Making Size or Quantity More Convenient.	
Improving the Package.	
Putting Sales Value into the Name.	
Adding New Items or Lines.	
Associating the Product with Others.	
Reducing or Simplifying Lines.	
Standardizing Quality.	
Price Lining.	
Utilizing Waste or By-products.	
Supplying Full Directions for Use.	
Service Features.	
Merchandising Problems in All Lines of Business.	
Factors Influencing Consumer Demand.	
Trends in Product Adaptation.	
Research to Find Out What Consumer Wants.	
Methods of Determining Consumer Demand.	
Style Information.	
Style Specialists.	
Checking Trends in Competing Lines.	
Getting Opinion of Dealers.	
Advance Opinions from Possible Consumers.	
Reactions from Consumers after Trial.	
Sales Statistics.	
Style Indexes.	
Pooling of Statistics on Style Trends.	
Organization of Merchandising Activities.	

CHAPTER IV

PRICE MAKING AND PRICE POLICY. BY EDMOND E. LINCOLN	91
Influences Determining the Price Policy.	
Cost Factors.	
Conditions of Production.	
Conditions of Demand.	
Quality and Service.	
Relation to Market Prices.	
Reasons for Selling below Cost.	
Uniform Prices and Price Discrimination.	
Quantity Discount.	
Price Concessions.	
One Customer Only.	
Price Guaranties.	
Price Maintenance.	

CHAPTER V

CHOICE OF MARKETING CHANNELS. BY GORTON JAMES	102
The Balance between Market and Product.	
Elements of Consumer Preference.	
The "Bell-shaped Curves" of Demand.	
Steps in Choosing Marketing Channels.	
Work Backward from the Consumer.	
Advertising to the Consumer.	
Consumer Preference.	
Types of Retailing and the Markets They Serve.	
Stores Granting Credit and Making Deliveries.	
Cash-and-carry-stores.	
Robots or Vending Machines.	
Mail-order Selling.	
Canvassers.	
Choice of Type of Outlet.	
The Various Kinds of Retail Stores.	
Choice of Intermediate Channels.	
Selling with Own Sales Force.	
Contracting with Sales Agent or Factor.	
Selling through Brokers.	
Selling on Consignment.	
Industrial Markets.	
The So-called Marketing Revolution.

BY D. W. HARRIS	327
Importance of Broad Viewpoint.	
Duties of the Financial Executive.	
The Financial Statement.	
The Financial Executive and the Budget.	

CHAPTER II

FINANCIAL PLANNING AND CONTROL

FINANCIAL AND INDUSTRIAL ANALYSIS. BY DWIGHT T. FARNHAM	33
Bases of Financial Management.	
Standardization of Financial Statements.	
Financial Investigations.	
The Ratio Method of Financial Analysis.	
Frequently Used Ratios.	
Supplementary Ratios.	
Analysis of Working Capital.	
FINANCIAL BUDGETING TECHNIQUE. BY CHESTER E. WEGER . .	340
What Constitutes a Financial Budget.	
The Banker's Confidence in the Financial Budget.	
Method of Handling Construction Program.	
PRICE FLUCTUATIONS IN RELATION TO BUDGETING. BY J. B. DEACON	347
Budgeting Procedure of an Oil Company.	
Effect of Price Changes upon Forecasts.	

CHAPTER III

INCORPORATION AND THE POSITION OF THE STOCKHOLDER

THE INCEPTION OF THE CORPORATION. BY K. O'MALLEY	363
Corporation Defined. Its Advantages.	
Corporation Not a Partnership.	
Corporation Not a Joint Stock Company.	
Purposes.	
Stock and Non-Stock.	
Function of Promoters.	
Forming a Corporation.	
The Controlling Law.	
Notice of Intention.	
Preparation of the Charter.	
Filing the Charter.	
Issuance of the License.	
Organization Procedure.	
Fees and Taxes.	
Initial.	
Annual.	
Choice of a State.	

STOCKHOLDERS: THEIR RIGHTS AND DUTIES. BY A. A. BERLE, JR.	PAGE 374
What is a Stockholder?	
Classification of Stockholders.	
Limited Preferred Stock.	
Participating Preferred Stock.	
Non-cumulative Preferred Stock.	
Common Stock.	
"Split" Common Stock.	
Stock Purchase Warrants.	
The Stockholder's Position in the Corporation.	
Stockholders' Rights.	
Stockholders' Duties.	
The Unsolved Position of the Stockholder.	
Accountability of Management to Shareholders.	
Summary of Position.	

CHAPTER IV

BOARDS OF DIRECTORS, BOARD COMMITTEES, AND OFFICERS

FUNCTIONS OF BOARDS OF DIRECTORS, BOARD COMMITTEES, AND OFFICERS. BY JAMES O. MCKINSEY	391
Conditions Determining Functions.	
Functions of the Board.	
Relation to Objectives and Policies.	
Relation to Organization Problems.	
Checking Efficiency of Organization.	
Composition of the Board.	
Functions of Committees of the Board.	
Officers of the Board.	
Relationship of Chairman to President.	
Duties of the President.	
The Treasurer.	
TRENDS IN THE FUNCTION AND COMPOSITION OF BOARDS OF DIRECTORS. BY ERWIN H. SCHELL	401
Size of Boards.	
Connection of Directors with the Business.	
Occupations of Directors.	
Reasons for Presence on Board.	
Number of Meetings.	
Fees and Profit Sharing.	

	Page
THE FINANCE COMMITTEE. BY JAMES O. MCKINSEY	412
Reasons for Establishment.	
Responsibilities.	
Composition.	
Relation to Executives.	
THE COMPTROLLER. BY J. P. JORDAN	416
Comptroller's Department.	
Specific Duties.	
Personal Characteristics.	
Exercise of Responsibility.	
Organization of Department.	
FUNCTIONS OF THE AUDITOR. BY C. E. JARCHOW	424
FUNCTIONS OF THE CHIEF ACCOUNTANT. BY ARTHUR PERROW.	426

CHAPTER V

CORPORATE FINANCING, LONG TERM. BY A. C. HODGE 430

Recent History.	
Present Institutional Structure.	
Functions of the Investment Banker.	
Corporate Capitalization.	
Treatment of Intangibles Purchased.	
Securing Capital from Earnings.	
Purposes of Long-term Financing.	
Long Term Financing for Working Capital.	
Refinancing.	
Financing Improvements and Expansion.	
Consolidations and Mergers.	
Financing to Diversify Investment.	
Importance of Marketability.	
Other Factors in Withdrawal of Owner's Investment.	
Methods Employed on Financing Withdrawals.	
Stock with No Par Value.	
Trends in Investor Demand.	
Responsibilities of the Investment Banker.	
Financial Problems of Smaller Companies.	

CHAPTER VI

SHORT-TERM BORROWING. BY MARY RODGERS

LINDSAY	448
Methods of Short-term Borrowing.	
Unsecured Bank Loans.	

Sale of Promissory Notes on the Open Market.	
Discounting Trade and Bankers' Acceptances.	
Loans Secured by Stock Market Collateral.	
Commodity Loans.	
Assignment of Receivables.	
Installment Financing.	
Miscellaneous Methods.	
Estimating Short-term Requirements.	
Selecting the Method Used.	
Summary.	

CHAPTER VII

CONSOLIDATIONS AND MERGERS

TYPES OF CONSOLIDATIONS AND MERGERS. BY DWIGHT T. FARN-	
HAM	466
Corporate Types of Combinations.	
Those Based upon Stock Holding.	
Cartels, Trade Associations.	
Those Based on Common Interest.	
Legal Situation.	
Economic Developments Affecting Combinations.	
Economic Types of Combinations.	
Horizontal, Vertical.	
Allied Industry, Chain.	
Local, Seasonal.	
Cartel, Common Interest.	
Export Combinations.	
European Types of Combinations.	
International Combinations.	
FACTORS TO CONSIDER IN WORKING OUT MERGERS. BY A. D.	
BERNING	481
The Human Factor.	
Every Merger Is Different.	
Fundamental Factors.	
Economic and Legal Soundness.	
Management.	
Financial Position.	
Earning Power.	
Formula or Plan of Merger.	
Launching the Merged Business.	
Importance of the Budget.	
International Influences.	

	PAGE
POST MERGER ECONOMICS. BY THOMAS R. JONES	489
The Reasons for Mergers.	
Mergers Do Not Necessarily Bring Economies.	
Reasons for Uneconomical Results.	
Losses Incident to Effecting Economies.	
A Drop in Total Sales.	
Excess of Assets, New Investment, and Moving Expense.	
Inadequate Organization, Development Expense.	
Excess Personnel, Excess Financial Structure.	
Economies to Be Realized through Merging.	
Production Economies.	
Administration, Sales.	
Importance of Management.	
An Example of Results in an Actual Merger.	
Summary.	

CHAPTER VIII

DEPRECIATION AND OBSOLESCENCE. BY HAROLD VINTON COES	504
Definitions.	
No Accurate Rate of Depreciation Determinable.	
Causes of Obsolescence.	
Two Sound Ways of Dealing with Obsolescence.	
Caring for Depreciation.	

CHAPTER IX

INSURANCE AS A MANAGEMENT PROBLEM

INSURANCE INDEX: AN OUTLINE. BY P. D. BETTERLEY AND COMMITTEE	510
Basic Principles of All Insurance.	
Media of Indemnity.	
Contract Provisions.	
Regulating Factors.	
The Ultimate Test.	
Insurable Risks.	
Property Hazards.	
Liability Insurance.	
Earning Power.	
INSURANCE WITH SECURITY. BY P. D. BETTERLEY	516
Basic Principles of Insurance.	

CONTENTS

xxix

PAGE

Fundamentals of Good Contracts.	
Cooperative Procedure.	
Media of Indemnity.	
Types of Policies.	
Specific Insurance.	
Blanket Insurance.	
Coinsurance Contract.	
Guaranteed Amount.	
General Cover.	
Floater Policy.	
Automatic Insurance.	
Obligations of Contracting Parties.	
Third Party Interests.	
Special Policy Conditions.	
Cost-regulating Factors.	
Valuations.	
Settlement of Loss.	

Section 3

PRODUCTION MANAGEMENT

CHAPTER I

HISTORY AND FUNDAMENTALS OF PRODUCTION. BY	
CHARLES H. HATCH.	531
History of Production.	
Beginnings of Mass Production.	
Effect of Taylor's Work.	
Basis of Real Mass Production.	
The Single-purpose Machine.	
Four Types of Production.	
Misapplication of Mass Methods.	
Choice of Type of Production.	

CHAPTER II

ORGANIZATION OF THE MANUFACTURING DIVISION.	
BY PERCY S. BROWN	540
Establishing the Manufacturing Division.	
Functional Activities.	
Type of Organization.	

Grouping of Functions.	
Functional Responsibilities.	
Functional Authority.	
Establishing Policies.	
Selection of Personnel.	
Co-ordinating Departmental Interests.	
Relationship to Other Divisions.	

CHAPTER III

THE INDUSTRIAL PLANT. BY ROBERT P. KING . . .	548
---	-----

Location.	
Geographical.	
Local.	
General Arrangement, Planning.	
Types of Plant Buildings.	
Types of Floors.	
Types of Roofs.	
Special Provision for Unusual Equipment or Processes.	
Building Accessories and Special Features.	
Construction and Installation.	

CHAPTER IV

PLANT LAYOUT. BY CHARLES H. HATCH	568
---	-----

Layout Depends on Type of Production.	
Functionalized Departments.	
Multiunit Plan.	
Combined Functional and Line Departments.	
Breaking Down a Functionalized Department.	
Dealing with Heavy or Bulky Parts.	
Flow of Materials.	
Traffic Lanes.	
Layout of Departments and Storerooms.	
Use of "Banks."	
Layout in Relation to Supervision.	
Repair Benches.	
Shapes for Secondary Flow.	
Spacing between Equipment.	
Maintenance and Service Departments.	

CHAPTER V

MACHINERY AND EQUIPMENT. BY W. S. POWERS . . 576

- Single Purpose vs. Standard Machines.
 - High Overhead on Single Purpose Machines.
 - Permanence of Design of Product.
 - Adopting the Latest Improvements.
- Basic Factors in Choosing Equipment.
 - Use of Labor or Machines.
 - Efficiency of Production vs. Cost of Equipment.
- Determining Number of Machines.
 - Problem of Number of Shifts.
 - Probability of Obsolescence.
- Choice of Material-handling Equipment.
 - Reduce Handling of Materials to Minimum.
 - Material-handling Problems.
 - Moving Materials between Operations.
 - Conveyors for Assembly Work.
- Power Lines.
- Communication Methods.
- Time Recorders.
- Dies, Jigs and Patterns.

CHAPTER VI

RESEARCH, DEVELOPMENT, AND DESIGN. BY R. G.

CASWELL 589

- Research Must Be Correlated with Marketing.
- Research Organization Must Be Developed.
- Scope of a Technical Department.
- Importance of Semiworks Study.
- Summary of Functions in Sequence.
- Patent Not Always Desirable.
- Research Appropriations Based on Gross Sales.
- Average Costs per Man per Annum.
- Control of Expense of Research.
- Accounting Difficulties.
 - Method of Evaluating Accomplishment.
 - Use of Monthly Time Sheet.
- Time Limit for Crediting Savings.
- Growth of Organized Research.

CHAPTER VII

PRODUCTION CONTROL. BY GEORGE T. TRUNDLE, JR. 604

- Major Divisions of Production Control.
 - Planning.
 - Routing.
 - Scheduling.
 - Dispatching.
- Production Control Best Term.
- Production Control Defined.
- Need for Production Control.
 - Service to Customers.
 - Securing Lowest Costs.
- Essentials for Complete Control.
- Installation of Production Control.
 - General Plan.
 - Master Schedule.
 - Forms for Records.
- Departmental Control.
 - Analysis of Operations.
 - Planning and Controlling Labor and Material.
 - Controlling Equipment, Tools, Patterns and Molds.
 - Plant Layout.
 - Economical Lots.
 - Production Standards.
- Relationship of Production Control to Other Functions.
- The Production Control Staff.
- Cost of Production Control.
- Forms and Systems.
- Graphics.
- Symbolization.
- Application of Production Control to Various Classes of Industry.
- The Small Shop.
- Summary of Possible Results.

CHAPTER VIII

MOTION STUDY. BY LILLIAN M. GILBRETH 628

- Motion Mindedness.
- Determining Need for Motion Study.
- Characteristics of Motion-study Analyst.

The Motion-study Technique.	
The Process Chart.	
The Micromotion Method.	
Micromotion or Stop-watch.	
Who Should Be Filmed?	
The Michrochronometer.	
Preparation for Filming.	
Attitude of Workers.	
How Much to Record.	
The Simo Chart.	
The Therbligs.	
Arrangement of the Work Place.	
Use of Micromotion Study.	
The Cyclograph.	
Aims and Results of Motion Study.	

CHAPTER IX

INCENTIVES AND SUPPLEMENTARY WAGE PAYMENTS

INCENTIVE PLANS FOR DIRECT AND INDIRECT LABOR. BY KENNETH B. ANDERSEN	644
Need for Incentives.	
Kinds of Incentives.	
Purposes of Incentives.	
Measuring Response.	
Variety of Wage Plans.	
Limits of Variations in Plans.	
Details of Wage Plans.	
Location of Task.	
Straight Time-payment Plans.	
Piece-rate Plans.	
Gain-sharing Plans.	
Empiric Plans.	
Danger of Classifying Wage Plans.	
Uses of Straight Time Payment.	
Advantages of Piece-rate Plans.	
Advantages of Gain Sharing.	
Advantages of Empiric Plans.	
Selection of Wage Incentive Plans.	
Selecting the Elements of Response.	
Labor Factors.	
Management Factors.	

Cost Factors.	
Installation of Wage Incentives.	
Maintaining Standard Conditions.	
Wage Incentives in Drafting Tool and Machine Departments.	
Maintenance Departments and Other Indirect Labor.	
The Factory Office.	
EXTRA FINANCIAL INCENTIVES FOR SUPERVISORS. BY E. E. BRINK-	
MAN.	660
Classification of Incentive Plans for Supervisors.	
Factors Measured.	
Individual and Group Applications.	
Making the Foremen's Incentive Effective.	
Plan of the Holeproof Hosiery Company.	
SETTING THE BEGINNING WAGE FOR JOBS ON INCENTIVE WAGE PAY-	
MENT PLANS. BY E. H. LITTLE.	668
Hiring Rates for Inexperienced Employees.	
When to Pay Day Work.	
Training Allowance.	
How to Arrive at the Training Allowance.	

CHAPTER X

QUALITY AND INSPECTION. BY ROBERT W. KENT . .	671
Uses of Inspection.	
Control of Quality.	
Organization of Inspection.	
Measured Quality.	
Classes of Inspection.	
Place of Inspection in the Organization Chart.	
Standards of Quality.	
Types of Inspection.	
Control of Dimensional Quality.	
Enforcement of Quality Standards.	
Reduction of Scrap.	

CHAPTER XI

OPERATING DATA FOR LINE OFFICIALS. BY F. L.	
SWEETSER.	681
Manufacturing Costs.	
Standard Costs.	
Organization of Personnel.	

CONTENTS

XXXV

PAGE

Setting Standards.	
Raw Material Standards.	
Direct Labor Standards.	
Manufacturing Expense Standards.	
Standards for Special Conditions.	
Distribution Expense Standards.	
Cost Calculations.	
Variations from Standard Cost.	
The Accounting Procedure.	
Control.	
Analysis.	
Informative Reports.	
Budgets.	

CHAPTER XII

PURCHASING. BY EDWARD T. GUSHÉE AND F. A. COMPTON	704
Importance of Purchasing.	
Functions.	
Administration.	
Order Division.	
Economics Division.	
Accounting Division.	
Inspection Division.	
Salvage Division.	
Stores and Traffic.	
Basic Principles.	
Centralization.	
Personnel.	
Records.	
Coordination.	
Know What You Buy.	
Standards and Specifications.	
Fair Dealing.	
Conclusions.	

CHAPTER XIII

STORESKEEPING. BY STANLEY P. FARWELL	720
General Requirements.	
Centralized or Decentralized Stores.	

	PAGE
THE HEALTH OF OFFICE WORKERS. BY DR. LEVERETT D. BRISTOL	819
The Office Worker as an Individual.	
The Environment of Office Workers.	
Essentials of an Industrial Health Program.	
Management's Opportunities and Responsibilities for the Health of Office Workers.	
OFFICE WORKING CONDITIONS AND EXTRA COMPENSATION PLANS. BY H. J. TAYLOR	828
Hours of Work.	
Vacations.	
Compensation for Time Off.	
Compensation and Promotion.	
Special Privileges.	
Services for Employees.	
Summary of Standard Practices.	

CHAPTER IV

SALARY ADMINISTRATION AND PROMOTION. BY H. B. BERGEN	855
Need for Scientific Salary Administration and Promotion.	
Methods of Procedure.	
Job Analysis and the Establishment of Class Specifications.	
Objectives of Job Analysis.	
How Analysis Should Be Made.	
Actual Preparation of Position Specification.	
Grading of Classes of Positions.	
Class Grading Plan.	
Grade Description Method.	
Method of Rating Classes of Positions.	
Grade Progression Method.	
Establishment of Salary Schedules.	
Evaluating Capacities and Abilities of Individuals.	
Methods of Making Adjustments.	
Salary Adjustments.	
Promotional Adjustments.	
Responsibility of Line Executive in Salary Administration.	
Interpreting Salary Policies and Decisions.	
Relationships with Subordinates on Salary Matters.	
Technique of Writing Class Specifications.	

CHAPTER V

MEASUREMENT OF OFFICE OUTPUT

UNITS OF MEASUREMENT FOR OFFICE WORK. BY WALLACE CLARK 882

Quality Standards.

Units in Handling Papers.

Units in Correspondence and Typing.

Units in Clerical and Statistical Work.

Units in Accounting.

THE TECHNIQUE OF DETERMINING THE "ONE BEST WAY." BY

B. EUGENIA LIES 888

Analyzing Present Methods.

Selecting Best Elements.

Synthesizing into One Best Way.

DETERMINATION OF WORK UNITS FOR OFFICE MACHINES. BY

I. O. ROYSE 895

Graphotype, Addressograph, Flexotype.

Multigraph, Mimeograph, Ditto.

Hoover Typewriters.

Billing Machine.

Results of Use of Measurement.

MEASUREMENT OF OFFICE OUTPUT. BY JOHN MITCHELL 904

Units of Measurement.

The Operating Cycle.

Procedures and Time-study Sheets.

Typists and Operators Using Transcribing Machines.

Addressing Machines.

Cutting Stencils and Plates.

Duplicating Machines, Gelatin Rolls.

Conclusions from Measurement Survey.

Measurement Studies.

Output of Transcribing Machine Operators.

Output of Duplicating Machine Operators.

Output of Addressing Machine Operators.

Output of Typists Including Stenographers.

Output of Operators Cutting Stencils or Embossing Plates.

MEASURING, STANDARDIZING AND COMPENSATING FOR OFFICE

OPERATIONS. BY MARION A. BILLS. 918

Increase in Clerical Work.

No Relation between Size and Efficiency.

Need for Standardization.

Cost of Exceptions.

Use of Small Independent Units.

Checking in Total.	
Use of Surplus Time.	
Obtaining the Best Clerical Effort.	
Classification of Jobs.	
Importance of Measurement.	
Training Supervisors to Think in Terms of Cost.	

CHAPTER VI

OFFICE SERVICES. BY EDITH KING DONALD.	931
--	-----

Factors Determining Specialization.	
Safeguards on Centralized Service.	
The Supervisor of Office Services.	
Danger of Overcentralizing.	
Advantages and Disadvantages of Centralized Service.	
Filing.	
Sample Classification.	
Standardization through a Manual.	
Sample Work Routine for Filing.	
Combining Mail and Filing Departments.	
Mail.	
Messenger Service.	
Duplicating.	
Stenographic Service.	
Computation.	
Telephone, Telegraph, Radio.	
Reception of Callers.	

CHAPTER VII

FORMS: THEIR DESIGN AND USE. BY B. EUGENIA LIES	944
---	-----

Elements of the Problem.	
Purpose of Forms.	
Information Needed to Design a Form and Determine Specifications.	
Recording the Information.	
Using Information Previously Recorded.	
Handling the Form.	
Principles of Good Form Design.	
Specifications of Forms.	
Paper.	

Size of Form.	
Ink.	
Type.	
Ruling.	
Carbon.	
Binding.	
Numbering.	
Punching.	
Perforations.	
Methods of Controlling Forms.	

CHAPTER VIII

OFFICE PLANNING AND CONTROL

OFFICE LAYOUT. BY ORRIN G. SHERMAN	961
The Purpose of Proper Office Layout.	
Cost of Space.	
Other Losses Not Always Evident.	
Outline of Technique of Layout.	
Space Standards.	
Some Comments on Moving.	
PLANNING AND SCHEDULING OFFICE WORK. BY EVELYN M. DAVIS	964
Need for Planning and Scheduling.	
Basic Plans Not Enough.	
Part Played by Department Head.	
Lack of Standards of Production.	
Lack of Control.	
Creation of a Planning and Scheduling Department.	
Planning Unit and Control Unit.	
Personnel Unit.	
Special Planning Problems.	
THE CONTROL OF OUTPUT IN OFFICES. BY WALLACE CLARK. . .	974
A Method of Locating Obstacles.	
Control in Various Departments.	
Removing Mental Obstacles.	
COMPUTING AND CHARGING OFFICE COSTS. BY H. J. TAYLOR . .	979
Control of Costs in Jewel Tea Company's Office.	
Control of New Work.	
Progress Reports.	
Results.	
BUDGETING OFFICE EXPENSE. BY HADAR ORTMAN	989
Specific Application in Order-handling Department.	

	PAGE
INTRODUCING THE NEW EMPLOYEE. BY EARL B. MORGAN.	1106
Instruction.	
Introduction.	
Follow-up.	
LABOR TURNOVER. BY LLOYD R. MILLER	1110
The Problem and Its Causes.	
Analyzing the Causes.	
Reducing Labor Turnover.	
THE DISMISSAL WAGE. BY E. H. LITTLE	1117
Reasons for Paying.	
To Whom Paid and Amount.	
Continuous Service.	
Benefits from Payment.	
SELECTING AND PLACING COLLEGE MEN IN BUSINESS. BY JOHN MILLS.	1120
Specifications for Employment.	
Importance of Unhurried Interview.	
Questions Which Indicate Aptitudes.	
COLLEGE WOMEN IN BUSINESS. BY LOUISE MOORE.	1127
Data from Questionnaire.	
Employers Objections to College Women.	
Remuneration.	

CHAPTER IV

JOB ANALYSIS FOR POSITION CLASSIFICATION

CLASSIFICATION AND COMPENSATION PLANS. BY E. O. GRIFFEN- HAGEN.	1135
Definitions.	
Uses of a Classification Plan.	
The Process of Classification.	
Notes on Current Practice.	
INSTALLING A SALARY ADMINISTRATION PLAN. BY E. H. LITTLE .	1144
Outline of the Plan.	
Gathering the Necessary Information.	
Classification of Positions.	
Salary Standards.	
Salary Adjustments.	
THE PSYCHOLOGICAL ASPECT OF JOB ANALYSIS. BY RICHARD S. UHRBROCK.	1153
Nature of Job Analysis.	
Qualifications of Analyst.	
Psychological Aspects.	
Determining Significant Character Traits.	

CHAPTER V

COMPENSATION AND INCENTIVES

WAGES AS INCENTIVES. BY ELLIOTT DUNLAP SMITH	1159
Time Payments.	
Payment for Work Done.	
Standard Time Rates.	
Group Rates.	
Choice of Plan.	
General Principles.	
NON-FINANCIAL INCENTIVES. BY ROBERT B. WOLF.	1168
Use of Records Measuring Accomplishment.	
Kinds of Progress Records.	
Use of Individual Records.	
Use of Cost Records.	
Value of Non-financial Incentives.	
GROUP INCENTIVES. BY C. C. BALDERSTON	1182
By-products of Group Incentives.	
Problems Peculiar to Group Incentives.	
Distribution of Group Earnings.	
SUGGESTION SYSTEMS. BY A. B. GATES.	1187
Establishment of the System.	
Organization and Set-up of the System.	
Operation of the System.	

CHAPTER VI

SUPERVISION

SUPERVISORS: QUALIFICATIONS AND SELECTION. BY EDWARD DANA	1193
THE FOREMAN AS MANAGER. BY L. A. SYLVESTER	1196
Common Faults of Foremen.	
The Foreman as a Manager.	
Records and Results.	
RATING SUPERVISORS. BY HARVEY G. ELLERD.	1200
A Rating System.	
Tendencies of the Raters.	
Correcting Elements Lacking in Men.	
Measuring a Man's Ability.	
WOMEN IN SUPERVISORY POSITIONS. BY E. H. LITTLE	1206
Source of Successful Supervisors.	
The Forewoman's Handicaps.	
A Woman's Assets and Liabilities.	

Contributory and Non-contributory Pensions.	
Extent of Pension Benefits.	
Terms of Pension Plans.	
Cost of Industrial Pensions.	
METHODS OF FINANCING PENSION PLANS. BY GILBERT E. AULT	1346
Basic Precautions.	
Methods of Financing.	
At Retirement on Pension.	
By Single Premium Group Annuities.	
By Level Percentage of Pay Roll.	
By Annual Premium Group Annuities.	
At Appointment to Service.	
FINANCING PENSION PLANS. BY JOSEPH H. WOODWARD.	1354
Costs and Reserves.	
Formulae for Costs and Reserves.	
High and Low Rates of Withdrawal.	
Illustrative Tables.	
Advantages of Tabular Reserves.	

CHAPTER IX

FINANCIAL PLANS FOR EMPLOYEES

EMPLOYEE INVESTMENTS IN COMPANY SECURITIES. BY GLENN A. BOWERS	1385
Extent of the Practice.	
Structural Forms.	
Extent of Participation.	
Benefits to Be Secured.	
Employee Investment Trusts.	
Type of Stock to Be Offered.	
Main Features of Plans.	
Administration of Plans.	
SAVINGS PLANS FOR EMPLOYEES. BY H. GILBERT FRANCKE . . .	1399
Security First Essential.	
Types of Plans.	
Results of Plans.	
THE CREDIT UNION. BY ROY F. BERGENGREN.	1403

Choice of Media.

WHAT SHOULD BE PRINTED IN EMPLOYEE MAGAZINES. BY STERLING PATTERSON 1407

Purposes of Employee Magazines.

Importance of Labor Policy.

Complexion of the Audience.

The Editor and His Status.

Common Faults of Such Publications.

INDUSTRIAL TOWN-SITE DEVELOPMENT AND ADMINISTRATION. BY THOMAS A. McDONALD 1412

Need for Town-site Developments.

Importance of Initial Plans.

Standard Requirements.

Forecasting the Pay Roll.

Determining Number and Type of Houses.

Permissible Rental.

Physical Layout of Town.

Problems of Administration.

CHAPTER XI

COLLECTIVE BARGAINING WITH UNIONS. BY F. A. SILCOX 1421

Determination of Policy.

Effects of Unionism.

Closed Shop and Open Shop.

Stabilization of Costs by Union Contract.

Union Functions.

Union Leadership.

Intra-union Problems, Inside Politics.

Inter-union Problems, Jurisdictional Disputes.

Labor Banks.

Unions and the Immigrant.

Collective Bargaining: The Contract.

Administration of the Contract.

Strikes, Boycotts and Union Label Disputes.

Arbitration.

Defining the Issue.

Decentralized Responsibilities.	
Establishing Standards of Operation.	
Providing Staff Assistance.	
Functionalization Defined.	
Incentives for Executives.	
Developing the All-round Executive.	

CHAPTER II

THE TECHNIQUE OF MANAGEMENT REQUIRED TO MEET RAPIDLY CHANGING CONDITIONS. BY PEARCE C. KELLEY	1510
---	------

How Management Meets Changes.	
A Fact-founded Operating Organization.	
What Changes to Look For.	
Where Will Rapid Changes Occur?	
Sources of Information on Changes.	
Provision for Use of Information on Changes.	
Summary of Essentials.	
Forecasting and Anticipating Rapidly Changing Conditions.	
The Flexible Budget.	
Business Forecasting.	
Maintaining a Sensitive and Flexible Organization.	
Organization for Deciding on Adjustments.	
Maintaining Flexibility for Making Adjustments.	
Method of Deciding What Adjustments to Make.	
Summary.	

CHAPTER III

MANAGEMENT CONTROL

ELIMINATING IRREGULARITY OF OPERATION. BY HERMAN FELD- MAN.	1531
--	------

Perfect the Sales Side First.	
Distribution Policies that Promote Steady Operation.	
Organizing Production within the Plant.	
Personnel Policies that Promote Steady Work.	
A Rounded Out Program Essential.	

ESSENTIALS IN BUDGETING. BY FRANK L. SWEETSER	1536
---	------

Why Have a Budget?	
Preparation, Conference Groups.	
Setting Standards.	

CONTENTS

liii

Taxes.	

THE SCOPE OF PUBLIC RELATIONS WORK IN INDUSTRY. BY LEON

V. QUIGLEY 1704

Origin of Public Relations Work.	
Interpretation of Scientific Achievements.	
Standards.	
Classification of Public Relations Work.	
Principles of Procedure.	

FUNDAMENTALS OF COMPANY PUBLICITY. BY RICHARD D. HEBB. 1709

Who is "the Public"?	
Publicize a Person, Not a Corporation.	
Institutional Advertising.	
Timeliness of Material.	
Publicity Must Have News Value.	
Viewpoint of the Reader.	
Training for Publicity Man.	
Handling Adverse Comment.	
Desirability of Direct Contact.	
Handling News Releases.	
Reports on Publicity Work.	
The Branch Manager.	

INDEX. 1719

must consider whether it is wise to aim for vast achievements in the large-scale operation and run the risk of obscurity which is attendant upon mediocrity, or whether it is better to aim for larger and quicker recognition in small-scale operations and perhaps have little or no opportunity for large rewards.

Because of the rapid increase and rapid growth of big business, the conduct of each individual business naturally has wider and wider effects on other businesses, big and little. These effects are in three general directions.

The management of each individual business has a direct effect on all who buy from or sell to it, from the producer of raw materials to the ultimate consumer.

The management of each individual business has a direct effect on the operations of all in competition with it. Marginal producers who do not know their costs represent ignorant competition. Those businesses which set out to dominate an industry by truculent methods represent unfair competition. This competition may be for materials as well as for consumers, for employees as well as for distributors.

The proper financing of a business has a definite relationship to regularity of employment. Companies follow practices out of sheer necessity which they would not follow if they were in a position to maintain the proper kind of balance sheet. Inadequately financed companies are almost certain to be those which cannot afford to manufacture for stock out of season. Consequently, employees suffer the deprivations which are inevitably associated with seasonal irregularities of production and employment.

In a period of business stress those companies which are inadequately financed are forced to abandon personnel not absolutely needed at the time and to sacrifice their investment in selection, training, development and promotion. They have no other choice. A corporation properly financed might in a period of business stress take delayed action in eliminating from the organization men who should not have been kept on so long, but it takes no steps whatever to eliminate key men just because of current business conditions.

A recession in business becomes the occasion for directing the efforts of such men into channels which would ordinarily have to be neglected during a period of normal business.

Budgeting, one of the accepted techniques of modern business administration, has a very important social and economic influence, not only because of its effect on the company itself, but also because of its effect on other companies and on business in general. The company without a budget and unable to make comparisons of results against estimates is in danger of overexpansion in a period of favorable conditions and is in equal danger of becoming timid and of making altogether too drastic curtailments in a period of business recession.

The budget provides a plan for a certain period of time, usually in considerable detail for a six to twelve months period and in less detail for a period of two or three years in advance. With such a tool of administration at hand it is possible to look over a long period with some degree of equanimity and adopt policies in regard to executive and rank and file personnel that are constructive not only for the company but also for the community.

A company lacking a budget cannot view its affairs from the long run point of view and is in danger of adopting policies and practices which contribute to and aggravate the social problem of unemployment, decrease of consumer purchasing power, and all of the other social and economic evils which attend a period of business uncertainty.

Budget comparisons permit an analysis of business operations which lead to the discovery of sound economies, not of those imaginary economies which should not be made because they would affect activities or production in such a way that sales and income would be adversely affected.

Advertising programs can be conducted in such a way as to help stabilize business and employment. While it is generally true that companies advertise more freely when business is good, nevertheless, an increasing number of companies are setting up a reserve when business is at the highest point, a reserve which is thrown into action when business is not so good. This advertising program helps to stabilize the particular business, to maintain employees of the particular company, to maintain purchases during a period of business recession, to maintain employees' consumer purchasing power and thus favorably to affect the market of other producers while at the same time alleviating, so far as one company can, the social problem attendant upon unemployment.

The ramifications of business administration in the economic and social structure are gradually becoming so well recognized that each year public, employees, and management itself are coming more and more to regard management as a profession with public obligations.

The responsibilities of management to the personnel of an organization appear more and more in various forms through the adoption of a minimum guarantee of employment, voluntary company insurance plans, in the form of pensions, group insurance, accident prevention, sickness prevention and health education, through efforts to regularize employment, not only seasonal unemployment but also cyclical unemployment, and in training employees for increased efficiency.

That this public obligation of management is recognized in America is indicated by the fact that American corporations are in growing numbers voluntarily adopting standards of responsibility to employees more favorable to employees than the minimum guarantees provided for by legislation, not only at home but also abroad.

In fact, this tendency for business administration to adopt policies and practices in excess of legislative requirements is one of the truest indications that in America at least management is emerging as a profession because, after all, one of the indices of a profession is that it recognizes its responsibility to the public.

Another point at which business administration is affected with public interest lies at the point at which it must coordinate the effects of technological developments and the interests of the consumer, stockholder, and employee. It is increasingly recognized that business problems are being solved soundly when they are solved in the interests of the consumer, for whom, after all, fundamentally a business and all business must exist. The consumer interest is not served by restraint on technological improvements which

postpones unduly the benefits which may accrue to the consumer from improved methods which produce a better product.

In this connection, it is important to note that the only complete study of the effect of technological changes on unemployment that has yet been made indicates that mechanical developments, while they have reduced the required amount of unskilled labor, have increased the demand for skilled labor. They have also led to a grading up of the work and an increase in the earnings of what had formerly been a large part of the unskilled labor.

Another social aspect of business administration lies in the comparatively widespread distribution of the ownership of the modern business. Since 1920 the number of stockholders in American corporations has increased several times, there being many instances of corporations whose stockholders today number anywhere from ten to twenty times as many as in 1920. Many of these stockholders are employees of the corporation itself. An equally large number, probably a larger number in most cases, are employees of other companies. Of the remainder a certain proportion are the traditional widows and orphans, and the balance are financial and other similar investing institutions and individual capitalists. As managers are trustees for stockholders, certainly this distribution of securities is taking on new aspects quite unanticipated in the era of ownership management. Nor is that public, and therefore social, responsibility likely to decrease in the long run.

Nor is the interest of the consuming public likely to remain as unorganized or as incoherent as at present. Undoubtedly the day will come when the consumer investor will find ways and means of expressing himself so that public attitude will be more and more favorable toward successful, profitable corporations. More and more the interest of the consumer in a serviceable product at a fair price, efficiently produced and marketed will merge with the interests of the same consumer as stockholder in a business which is profitable because it serves the consumer well.

"Surveys" are being sold as cure-alls for marketing ills. The medicine man is having his day.

Before we can hope to get any adequate concept of the true function of market research and analysis, it is necessary to clear the air of all this biased pursuit of information, this opportunistic problem pecking, and to inquire whether or not research can be used to promote the soundness of marketing decisions.

Any marketing manager¹ must make a series of decisions whether he wants to or not. Many of the conditions involved in these decisions are unknown. Many not measured. Many immeasurable in any concrete sense. He can never hope to get enough information about his markets to give perfect support to all his decisions. But neither can he afford to ignore any information that is readily available, or any that can be secured at a reasonable cost, if that information will help him to reach better-informed decisions.

What Kind of Information Will Help the Marketing Manager? The marketing manager should welcome any information that will help him:

1. To define his present market situation together with the long-range trends which have led up to it.
2. To discover what major and underlying factors are dominating that situation and how these factors can be influenced or controlled.
3. To set up a plan for keeping in touch with the behavior of these dominating factors and for measuring the results of any efforts made to influence or control them.

It is the function of market research and analysis to provide such information.

Diagnosing the Market Situation. In attempting to diagnose a market situation one is in danger of becoming overenthusiastic about some bit of information secured early in his study and of being too quickly satisfied that he has hit upon the final solution to his problem. We are so accustomed to reading fairy stories about market research in which an interview with Mrs. Montgomery in Youngstown or with grocer Schultz in Detroit led to revolutionary changes in a company's marketing program, that we are likely to get the notion that information from one or two sources is sufficient basis for major decisions in marketing. But such is not the case.

In studying an industry, a manufacturer may observe that sales are increasing for the industry as a whole and, guided by this information alone, he may become unduly optimistic and plan to increase his volume of sales. But without studying in the market itself and without an analysis of production and marketing costs, it would be dangerous to assume that such an increase in volume could be secured at a profit. For a study among consumers may indicate that certain groups of consumers can be served more profitably than others. And an analysis of profits on various products will reveal which are the most profitable items. Such information may lead to a marketing program which will effect a reduction in sales volume and, at the same time, secure an increase in profits.

¹ Marketing manager is defined as the manager of advertising, sales, transportation, and any other activity involved in the movement of the product from producer to consumer.

In other words, the important decisions made by any marketing manager should rest upon a well-balanced diagnosis of his marketing situation. Such a diagnosis involves three general types of market study:

First, a study of the industry in which a company belongs, including problems common to every company operating in the industry, and the relative position of the company and of each competitor in the industry as a whole.

Second, a study of the company's problems from the inside out, including written records bearing on the company's marketing experiences, as well as unrecorded specifics in the minds of its employees.

Third, a study of the company's problems from the outside in, including the consumer market and the entire distributive system employed in carrying the company's products from producer to consumer.

I. STUDYING THE INDUSTRY IN WHICH A COMPANY BELONGS

Sources of Industrial Information. Most industries have come to realize that many of the marketing problems of individual companies in that industry are common to the industry as a whole. Some have organized associations. Almost without exception these industrial associations have for one of their primary objects the collection and exchange of market information intended to be mutually useful to all members of the association. Ordinarily, however, it is helpful to consult, in addition, such sources as the following:

1. Government bureaus.
2. Banks and investment companies.
3. Publishing companies.
4. Competitors.
5. Foundations.
6. Public libraries.

Gathering and Interpreting Industrial Information. Anyone who attempts to bring together the essential information available on an industry should have a thorough acquaintance with sources of information. He should be experienced in differentiating between fact and opinion. He should know the economic motives of the type of organization responsible for each piece of information that he gets and he should know how these economic motives are likely to affect the unbiased gathering and interpreting of market information. In dealing with industrial leaders among trade associations, publishing companies, or competitors, he should have the ability to inspire sufficient confidence on the part of those whom he interviews to get any "inside" information that has some relation to the present condition and future trends in the industry. He should, through it all, have a keen eye and ear for essentials.

The right man on the job is usually able to get some definition of the general dimensions of the industry, the size of the potential market, the long-range trends within that industry, and the general factors which appear to be dominating the industry as a whole.

As an example, a study of the baking industry will be presented. Space will not permit a presentation of the entire report. Under each heading, only enough information will be given to indicate the kind of material secured and the sources used.

The Baking Industry

Purpose. The purpose of this study of the baking industry is to analyze some of the more vital available statistical information as well as to summarize informed opinions secured from leaders in the industry.

The Product.¹ Prior to 1921, the only census information relative to bakery products was divided between the cracker industry and all other bakery products. However, from 1923 to 1927, the U. S. Biennial Census of Manufacturers has separated "bread, rolls, and coffee cake," and "cake, doughnuts, etc.," from "biscuits, crackers, and cookies," "pie," "pretzels," and "all other products." The relative importance which "bread, rolls, and coffee cake" and "cake, doughnuts, etc.," bear to the total industry is shown in the following table which expresses the percentage which their values bear to the value of the total industry.

A COMPARISON OF THE VALUATION* OF CAKE AND BREAD PRODUCTS
EXPRESSED AS A PERCENTAGE OF THE TOTAL VALUE OF ALL BAKERY
PRODUCTS

Year	Total value		Bread, rolls, and coffee cake		Cake, doughnuts, etc.	
	Amount	Per- cent- age	Amount	Per- cent- age	Amount	Per- cent- age
1927	\$1,236,976,348	100	\$693,922,151	56.1	\$227,307,364	18.4
1925	1,075,065,813	100	594,377,068	55.2	170,496,714	15.9
1923	1,122,906,314	100	631,325,019	56.2	190,251,607	16.9

* Only those firms who gave detailed information are included in these figures.

From "The Baking Industry," published by *Baker's Weekly*, we obtain the following:

"A typical cost sheet on bread production shows that 47 per cent of the cost is for ingredients. Flour is, of course, the major item . . ."

One leader in the industry told us:

"There is no outstanding problem which faces the industry so far as maintaining quality of product is concerned; by this I mean that most of the producers have formulas which are essentially similar and there is very little difference in the quality of the bread on the market today; to be sure some loaves cut better than others and some taste a bit different, but in the long run the bread on the market today is generally good.

"The producers face a big problem in the manufacture of cake. The fact that they have not yet been able to really perfect the eating quality of cake is a handicap to them. It is one of the reasons that they find it hard to break into the market. They have not yet learned the art of baking cake on large

¹ McCOLLUM, E. V., Sc.D., Ph.D., Department of Chemical Hygiene, Johns Hopkins University, "The Bread of Life," in *Baking Technology*, American Institute of Baking, vol. II, No. 9, p. 268.

FISHER, MORRIS, M.D., *The Journal of the American Medical Association*, "Bread as the Physician Sees It," an address delivered before American Baker's Association at Buffalo, New York, Sept. 17, 1925.

scale production so that it approximates the quality of home-baked goods . . . "

Production. In 1850¹ when the first census of manufacturers was conducted, there were reported to be 2,027 baking establishments employing 6,727 wage earners. Since 1850 the baking industry has grown rapidly. In 1850 the per capita value of bakery products was \$0.58. In 1927, the latest population estimates showed that the value per capita had risen to \$11.78. The population of the United States had increased 418 per cent in this period of time, and the value of bakery products per capita had increased 1,930 per cent.

At present, there are five different classifications of producers.

1. Large organizations engaged exclusively in the manufacture of bakery products and operating in a number of states—Continental, General, Ward, and others.

2. Chain store bakeries, like the Atlantic and Pacific, Kroger, and others.

3. Associations of bakers, like the Quality Bakers of America which is made up of independent wholesale bakers throughout the United States, chiefly east of the Mississippi.

4. Wholesale bakers who do a wholesale or combination wholesale and retail business and who are independent of the above three.

5. The small neighborhood bake shop primarily engaged in a retail business.

No figures are available which show accurately the percentage of total business done by these different types of producers. However, figures that afford the basis for a rough estimate are available. In a booklet entitled "Combinations in the Baking Industry," published by the Food Research Institute Publications, Stanford University, California, it is estimated that the following companies used 7,000,000 barrels of flour in 1925:

Continental Baking Corporation.
Ward Baking Company.
General Baking Company.
Purity Bakeries Corporation.
Southern Baking Company.
Cushman's Sons, Inc.

This figure represents approximately 25 per cent of the total flour consumption by the industry in that year . . .

The Market. Following is a tabulation derived from U. S. census data relating to the trend in per capita consumption of bakers' bread and cake:

PER CAPITA CONSUMPTION

Year	All products	Bread, rolls, coffee cake	Cake, doughnuts, etc.
1927	\$11.78	\$5.85	\$1.91
1925	10.99	5.16	1.48
1923	10.15	5.70	1.72
1921	10.11	*	*

* Figures not available until 1923.

¹ H. KYRK and J. S. DAVIS, "The American Baking Industry, 1849-1923," published by Stanford University, 1925.

electric vehicles . . . The 1925 census reported 9,713 bakeries using a total of 41,740 vehicles, divided as follows:

Horse drawn.....	8,991
Gasoline.....	28,879
Electric.....	3,870

A recent study made by the engineering staff of *Baker's Weekly* shows that the average expenditures for tires per day amounted to 64 cents for each truck. *Baker's Weekly* continues to say, "In fact, the average wholesale plant spends as much for tires as for oven fuel . . ."

With all wholesale bakeries, delivery is an important department. Twenty per cent of gross sales is regarded as a reasonable delivery cost. House-to-house bakeries, of course, have higher delivery costs . . .

Opinions of Industrial Leaders Interviewed. Confidential opinions offered by leaders in the baking industry were included at this point in the report.

These brief excerpts taken from a sample industrial study will indicate how a general acquaintance with printed information and informed opinion in relation to an industry as a whole, paves the way to an intelligent study of the market problems peculiar to an individual company in that industry.

II. STUDYING FROM THE INSIDE OUT

An internal study usually involves such sources of information as the following:

1. The marketing organization of the company.
 - a. Management and executive staff.
 - b. Sales force.
 - c. The advertising agency.
2. The sales costs and profits records of the company.
 - a. By products.
 - b. By territories.
 - c. By types of outlets and consumers.

Getting Unrecorded Specifics from the Marketing Organization. Those who have been in the advertising or sales organization for some time have had a favorable opportunity to observe long-range trends that affect the marketing of the product. Major and minor executives, including branch managers and sales supervisors, generally have, stored away in their minds, an immense amount of valuable information in the form of unrecorded specifics. While a full expression of ideas should be encouraged, yet it should be remembered that a large share of the information secured from this source is to be classified as opinion. In later field study these opinions can be subjected to the test of evidence.

Usable information can sometimes be secured from company salesmen providing some plan of conversation is followed that does not involve the personal interests or the ability of the salesmen. The experiences of some have led them to conclude that salesmen should never be used as a source of market information. But salesmen do possess specific information about the characteristics of sales territories which cannot conveniently be secured from any other source.

In all of these personal contacts, part of the job of the research man is to encourage members of the marketing organization (1) to appreciate the soundness of market analysis; (2) to strive for an effective application of the results of such analysis; and (3) to base, as far as possible, everyday decisions on impartial facts.

Analyzing the Company Records. Every company which has been marketing a product over a period of years has accumulated a wealth of information which, if properly analyzed, should help to locate some of the sales resistances that the company has encountered.

Sometimes the simplest kind of sales analysis furnishes an entirely new interpretation of sales experience. Let us take an example of the manufacturer who looked at his records and said "Sales are off in the Middle West." To begin with, this manufacturer is selling his product in two forms so that instead of selling one product he is really selling two products. A sales analysis showed that while total sales appeared to be off in the Middle West, sales on one form, *A*, of his product were increasing. But sales on the other form, *B*, were declining sufficiently to cause total sales to decline. Further analysis of declining sales on form *B* showed that they were not declining in the entire Middle West but only in the Chicago territory. Still further analysis showed that sales were not declining in the Chicago territory as a whole but only among one class of jobbers in this territory. So that what was called a decline in sales in the Middle West turned out to be a decline in sales of one form of the product to one class of jobbers in one territory.

Sometimes the simplest kind of cost and profit¹ analysis leads a company to emphasize its more profitable items and to direct its selling effort to those groups of consumers, and to those geographical territories, that can be served at the greatest profit.

Any established company can make a wide variety of studies based entirely on its records of sales, costs and profits. But in this brief treatment of market analysis, studies from the inside out will be discussed only in so far as they can be used to give sense of direction to, and facilitate the progress of, field studies that are designed to reveal what major factors influence the sale of a product.

Comparing Sales with Common Market Indexes. The case of X Company will be presented to illustrate the method of conducting a preliminary analysis of sales which leads to an intelligent selection of locations for field study. In the first place, a separate analysis was made for each product. Next, the following common market indexes² were used to reveal relatively high or low sales on each product:

¹ For a discussion of cost and profit analysis at various stages of volume increase, see discussion on total business situation, Chap. II, pp. 38-44.

² Available market indexes are used in this analysis solely to indicate relatively high or low sales. In handling these indexes one so inclined can easily juggle or weight them so that some combination conforms nicely with the sale of the product, but as long as the juggled index does not include the more important factors that influence the sale of the product, the conformance of the index is largely a coincidence—largely a case of "forcing the answer." When such a coincidence is accomplished, one is in danger of (1) overemphasizing the factors that so accommodatingly provide such smooth conformance, and (2) forgetting many other factors which may deserve an important place in explaining sales and in setting a basis for the intelligent improvement of sales.

**CHECK LIST OF FACTORS WHICH MAY AFFECT THE SALE AND THE
CONSUMPTION OF A PRODUCT**

- A. Factors related to market characteristics.**
 - 1. Natural conditions which may affect the sale of the product.
 - a. Climate.
 - b. Hardness of water.
 - c. Topography.
 - d. Proximity to ocean, sea, or river.
 - 2. Type of location.
 - a. Cities.
 - b. Towns.
 - c. Rural districts.
 - 3. Type of home.
 - a. Apartment.
 - b. Hotel.
 - c. Individual dwelling.
- B. Factors related to the product.**
 - 1. Possible uses of the product.
 - 2. Price of the product, constant or variable.
 - 3. Form of the product.
 - 4. Uniformity.
 - 5. Raw material used.
 - 6. Package or container.
 - 7. Trade name or brand.
 - 8. Style.
- C. Factors related to the consumer.**
 - 1. Classes of people.
 - a. Age.
 - b. Sex.
 - c. Income.
 - d. Education.
 - e. Occupation.
 - f. Nationality.
 - g. Race.
 - h. Religion.
 - 2. Buying habits.
 - a. Time and frequency of buying.
 - b. Quantity in which product is bought.
 - c. Product bought by brand name.
 - 3. Present uses.
 - a. Number of uses.
 - b. Kinds of uses.
 - 4. The consumer's familiarity with correct uses of product.
 - 5. Product likes or dislikes.
- D. Factors related to competitors.**
 - 1. The nature of competing products.
 - 2. Relative goodwill and strength of each competing product in different locations.
 - 3. Aggressiveness of each competitor.
 - 4. Their methods of selling, advertising, and transporting.
 - 5. Price differences between the product and competing products.
 - a. To consumers.
 - b. To trade.

E. Factors related to advertising.

1. Advertising media and methods used in different territories in the past and present.
 - a. To consumer.
 - b. To trade.
2. Advertising appeals used in different territories in the past and present.

F. Factors related to distribution.

1. The channels of distribution used in different territories.
2. The number, class, and location of brokers and jobbers.
3. Branch office and warehouse facilities.
4. Methods of transportation used.
5. Attitude of all dealers toward.
 - a. The product.
 - b. The advertising.
 - c. The company.
6. The buying habits of the trade.
 - a. Quantities in which product is bought.
 - b. Time and frequency of buying.
7. The number, class, and location of retail outlets.
 - a. Chain or independent.
 - b. Accessibility of retail outlets to the consumer.

G. Factors related to the company's sales organization in different territories.

1. Type and number of salesmen.
2. Use of brokers' salesmen.
3. Salesmen's routes.
4. Frequency of salesmen's calls.
5. Selection and training plan for salesmen.
6. Helps for salesmen.
7. Incentives for salesmen.

III. STUDYING FROM THE OUTSIDE IN

No extensive field investigation should be initiated until a preliminary study has been tried out on a small scale and, while limited in scope, this preliminary survey should not be hasty or superficial. It should rather be thought of as a period for thoughtful planning during which one (1) conducts a careful and thorough search for evidence on the factors which affect the marketing situation and (2) develops sound method for getting, at the lowest possible cost, whatever evidence is most significant and pertinent. The preliminary survey requires the services of a very few experienced investigators who have unusual powers of observation and the ability to sense the relative importance of new angles of the study as they are developed.

In this preliminary study it is necessary to secure only a limited number of interviews. But it is usually more fruitful to secure these interviews in three or four locations (preferably where sales are relatively at their best and at their worst) than to confine interviews to a single location. One can more easily discern factors which affect the sale of a product positively or negatively when he looks for those factors in locations where sales have been relatively high and in locations where sales have been relatively low. After trying out

5. At what time of the day, week, month, or year is the product usually bought?

6. Is the product bought as it is needed, or does the consumer wait for special sales?

Media

Definition. Media used in reaching the consumer direct, or the consumer through the dealer.

Sample questions:

1. What media seem to be most effective in reaching present and prospective consumers? (Newspapers, magazines, direct mail, outdoor, package inserts, general publicity, radio, house-to-house, personal contact, etc.)

2. What method of advertising seems to be most effective in reaching the consumer through the dealer? (Store demonstrations, window displays, inside-store and counter displays, premium sales, etc.)

Effects of Merchandising and Sales Service

Definition. Consumer attitude toward the merchandising and sales service offered by the company and its competitors.

Sample questions:

1. What is the attitude of consumers toward the terms offered by the company or by competitors?

2. What is the attitude of consumers toward the delivery service, or returned goods policy of the company and of competitors?

3. Does the sales service of the company really build goodwill in the minds of consumers by making them feel that the company's interest in the product does not stop with the sale of the product, but that the company is interested in seeing that the product gives the service promised?

4. Does the company's merchandising and sales service really stimulate sales?

Effects of Company Advertising

Definition. The effects of company advertising upon consumers.

Sample questions:

1. What percentage of those reached by various advertising methods are prospective customers?

2. Among what percentage of these prospects does the company's advertising produce the desired effect?

3. What are the relative costs of various advertising media in terms of available measures of results produced among consumers?

Characteristics of Competing Products

Definition. The characteristics on which the competition of other products is based.

Sample questions:

1. What consumer likes and dislikes are associated with each competing product?

2. For what purposes is each competing product primarily used?

3. Does the consumer think of my product as a substitute for competing products, or *vice versa*?

Do Not Freeze the Results of a Survey in Advance. In building a questionnaire to be used in a consumer investigation, one is in danger (especially if he has conducted a preliminary survey) of feeling that he knows enough about the information to be secured that he can build up a completely pre-coded questionnaire. To do so is to freeze the results of a study in advance.

Those interviewed are thereby led to give a stereotyped answer. Information thus secured drops nicely into prearranged pigeon holes and can easily be tabulated by machine. But such a procedure is likely to preclude the possibility of getting the kind of information that sometimes turns out to be most vital and surprising. To digress for a moment, let us recall the story of the old gentleman who passed by a little boy who was fishing. When he asked the youngster what he was fishing for, the answer came back, "Wooglies!" "Wooglies?" queried the old gentleman, "What in sam hill are Wooglies?" "I don't know," returned the youngster, "I haven't caught any yet." The investigator cannot be sure what he is going to find out. He is fishing for "Wooglies." Questions taken from a pre-coded questionnaire, that was used in a consumer investigation for a shoe manufacturer, should be sufficient to illustrate the principle.

This is the way it should *not* be done:

Questions	Code
Why do you like X shoes?	
Better looking.....	24-1
More comfortable.....	2
Not too heavy.....	3
Not too light.....	4
Wear longer.....	5
Why do you dislike X shoes?	
Do not wear well.....	25-1
Store service.....	2
Too expensive.....	3
Too heavy.....	4
Too light.....	5
Too stiff.....	6
Too unattractive.....	7
Too uncomfortable.....	8

If the like and dislike question is handled in the above way, the investigator is likely to use the possible answers listed as the basis for leading questions, and a check mark after one or more of these predetermined answers may be either insufficient or misleading.

If, on the other hand, likes and dislikes are secured by engaging a person in conversation and by recording the interview in the consumer's own words, the investigator will get a far truer picture of the consumer's attitude. Such an attitude may be: "Oh, I would just as soon wear X brand of shoes as Y brand. I have been wearing either one or the other for nearly six years now. I like the shape of the X shoe, but the Y shoe seems to support my foot a little bit better. But I think the X shoe is more stylish looking and it seems to me that it is easier to break in an X shoe. I usually buy my shoes at the Z

The Difference between Answers and Facts. Getting worthwhile information from the consumer is not a job to be handled by an amateur. Almost anyone can get answers to questions but one must be trained to get facts. The consumer is usually anxious to please the investigator and will frequently say whatever he thinks the investigator would like to hear. For this reason, the skilled interviewer knows that sometimes he must draw out the *facts*; he is not always satisfied with the first answer he gets to a question, for sometimes first answers do not coincide with the facts.

In one survey, for example, a manufacturer wanted to know whether or not the housewife had bought his product within the past ten days. In answer to this question one housewife said, "Oh, yes, I have a box in the kitchen now—I bought it only the other day." In order to be sure that she had really bought, the investigator wanted to *see* the box so he began to talk about the condition in which the package reached her. He said that the goods left the factory in good condition, but that he was always interested in knowing how they reached the consumer. She went to the kitchen to get the box and came back smiling with another brand of the goods in her hands. "Oh, say, this is Y brand that I bought the other day. I was thinking that it was X. You know there are so many different ones on the market that . . ." The housewife's first answer to the "Did you buy" question was "yes" but the *fact* was that she had not bought. This is one illustration of the difference between getting answers and getting facts.

Conversationalizing the Person Interviewed. Many market investigators seem to have taken literally Bacon's statement, "He that questioneth much shall learn much," and have made question boxes out of themselves. It is well to have questions in mind, but it is much better to secure information by engaging in conversation than by asking direct questions. The housewife, for instance, will listen to direct questions with patient and courteous attention, saying "yes" and "no" without really knowing what the interviewer is talking about.

If the interviewer does not appear too formal and too much like a newspaper reporter, he can in most cases "conversationalize" the person he is interviewing, i.e., make statements naturally related to the question, and so start the person on a voluntary stream of information that may reveal everything desired. The investigator should talk only enough to keep the other person talking. This method largely avoids the danger of asking leading questions. The market investigator will not be very successful in getting people to talk if he acts like the president of the company. His attitude should be one of an ordinary fellow who just works for the company, who is trying to get a general idea of things, and who needs lots of help. In fact, in some instances the more "dumb" he appears, the more information he will get. The trend of the conversation should not seem planned. It should be easy and natural. In order to get a person's confidence, the investigator must make some attempt to get on that person's level so that he or she is entirely at ease and willing to talk. The investigator should have a wide personality range that permits him to appear quite natural as he talks with various classes of people.

It Is Easier to Learn "What" than "Why." One should be aware of the general principle that it is usually much easier to find out *what* the consumer

does than to find out *why*. No one is conscious of all circumstances that led him to marry his wife. No housewife knows all conditions that caused her to buy for the first time or to continue to use a certain brand of baking powder. Even though one vividly remembers some of the conditions which surrounded the first purchase of a given product, he will hardly be able to analyze all conditions that influenced his choice or that caused him to continue using the product. This does not mean that consumers will not explain why they do things. They will. But they actually do not know the complete story and many of the reasons that they do give are the result of pride or rationalization. If price has dominated the choice of a product, the consumer may be reluctant to admit this even to himself and he may be still more reluctant to give this reason to anyone else. Even after a product has been bought, anyone can readily invent reasons for satisfying himself that he has made a wise choice, and it is these invented reasons that we sometimes get when we ask a consumer why he uses a certain product.

For example, take the following conversation between two housewives:

Mrs. A: What kind of baking powder do you use?

Mrs. B: X brand.

Mrs. A: Oh, I do too. I like it so much. It makes the texture of your cakes so fine.

Mrs. B: What's that? Fine texture? Oh, yes, of course—yes, it does make a fine-textured cake.

A little later the market investigator interviews Mrs. B. and she includes among her reasons for using X brand of baking powder, "It makes such fine-textured cake."

Even though reasons given by consumers to explain their attitude toward the product are so often invented reasons and so seldom complete, such information does shed some light on the marketing situation and, after careful evaluation, can be used for what it is worth.

What Does the Consumer Like to Brag About? Sometimes it is difficult even to find out *what* the consumer does. There are certain things that people like to brag about. Take the case of a manufacturer who was interested in the relative value of various magazines as advertising media for his product. He asked housewives, "To what magazines do you subscribe?" The housewife, anxious to reflect as much personal culture as possible, named over magazines which in her opinion one ought to read. And the manufacturer discovered, after an expenditure of a large amount of money, that the answers to this question were inaccurate and misleading.

What Does the Consumer Like to Soft Pedal? On the other hand, there are a great many things that the consumer is not very willing to talk about. One manufacturer, in trying to find out how housewives regarded special sales on his product, found that not all housewives who watched these special sales in order to save a few pennies would say that they did so. Another manufacturer of a quality food product found that it was not always easy to discover whether or not a housewife mixed his product with a cheaper product for household use.

These examples will suggest the difficulty of getting satisfactory answers to questions bearing directly on pride or class distinction, and will indicate why it is necessary to "conversationalize," rather than to ask direct questions.

What Can the Customer Remember? Ordinarily the consumer does not attempt to keep any record of his purchases. He may not be able to recall accurately how often he buys a product and in some instances he may even be vague as to the average quantity purchased at one time. Neither can the consumer be expected to recall whether or not a coupon, left several months before, has been redeemed or where he has seen a certain brand of product advertised. When the investigator asks questions which involve hazy recollections, consumers—even though their memory is faulty—usually make some attempt to give a definite answer, with the result that the investigator is in danger of recording unreliable information. As far as possible, a question should not be asked unless it can be answered in terms of easily recalled experiences.

Getting Information from the Retailer

Because the retailer occupies a key position in the distribution system, with frequent contact with both jobber and consumer, he is usually a valuable source of information.

In calls among retailers, one manufacturer found the sale of his product *shifting* from hardware stores to 5- and 10-cent stores. Still another found that the sale of his product was *spreading* to new kinds of dealers; that his product, heretofore sold only in grocery stores, was now enjoying an increasing volume in drug stores.

The retail store is the only place where manufacturers can find out what happens when consumer buying habits and retailer selling habits come together on the same stage and play their parts in the story of actual sales.

Following is an example of such a study in which a number of investigators each spent a day in a grocery store recording in shorthand the action and dialogue. Part of one report will be given merely to illustrate this method of getting information and to suggest its possibilities.

Grocery Stories

Apr. 2, 1930, 9:00 a.m. *A Consumer store located at the corner of Kimbark and 55th Streets, Chicago, Illinois. It is a clear, bright day. The woman manager, Mrs. Kohn, and the clerk who assists her, also a woman, are taking the monthly inventory. The store has one long counter on the left as you enter. There are shelves all around—all those except the one behind the counter easily accessible to the customer. The store has a neat, clean appearance, and everything is marked in some way to show the price. There are large ads at the top of the back and side shelves, advertising Consumer's 100 per cent Whole Wheat Bread, Hart Canned Foods, Gold Medal Coffee and Tea, Sandwich Bread, and Consumer's Best Eggs.*

Enter a middle-aged woman. They exchange comments on the subject of the customer's health, which seems to be failing.

Woman: One pound of Jelke's and one of good butter. Is that corned beef on sale today?

Clerk: Yes. (*Puts up some bulk corned beef.*)

Woman: One can of corn. (*Clerk gets White Cloud brand.*)

Old man enters.

Clerk: Yes, sir.

Man: A half-dozen fresh country eggs. No fooling, no city eggs. now.

Clerk: I just went out in the country to get them.

Man: A package of Uneeda Biscuit. (National Biscuit salesman finds out what I am doing—he has come in for order—and asks how many people have come in to ask for Uneeda Biscuit. I have only one. The clerk says that that particular man does not eat anything but crackers—no bread—so he is a good customer for Uneeda Biscuit.)

Enter man with little boy. He has a list of articles to be purchased.

Clerk: Good morning.

Man: Hello. A loaf of bread, please—large loaf. (Gets Better Bread, Consumer's brand—the only one they handle.) A dozen eggs—Best eggs Consumer's brand), a can of peaches.

Clerk: You want a large can, don't you?

Man: Yes, I want a large can. (Clerk gets him Hart brand.) And two bunches carrots, three cans vegetable soup. (Clerk gets Campbell's soup, the only kind on shelf.) Package of salted crackers.

Clerk: Twelve-cent package?

Man: Yes. (Clerk gets National Biscuit brand.) That will be all, I guess. (They converse a little about the heavy snow of previous week, and then the customer leaves.)

Colored man comes in. He picks up a package of National Biscuit cookies.

Man: Let me have some cheese. (Clerk gives him Kraft's.) Two cans of salmon. (Gets Wideawake brand. Customer looks at shelf, sees smaller cans, and asks about them.)

Clerk: No, those are 23 cents each. They are the red salmon. These (meaning the pink) are two for 23. (The customer seems satisfied.)

Man: Give me a few of those fig cookies.

Clerk: Ten cents worth?

Man: Yes.

Elderly woman enters the store.

Woman: I want some Dutch Cleanser.

Clerk: Kitchen Klenzer?

Woman: It's all the same, isn't it?

Clerk: It's 5½ cents or five for 27.

Woman: Give me three of them, I guess. (Studies a while.) Oh, I don't know, might as well take five. Let's see, I want some peas—a little can.

Clerk: You want two cans?

Woman: Yes. (Clerk gets Hart brand.) Then I want some prunes.

Clerk: A pound?

Woman: Yes.

Clerk: Do you want these in the little package (Sunsweet), or those in bulk?

Woman: The bulk. I guess that's all.

Clerk: Have you got bread enough?

Woman: Yes, we have bread. (Then picks up package of Leansweet bacon to put with order.)

Clerk: That is quite a full bag for you.

Woman: Uh-huh.

Clerk: Thank you.

Woman enters.

Woman: I want a small bag of flour.

Clerk: Better Bread? Ceresota?

Woman: Which is the best?

Clerk: The Better Bread is very good flour.

Woman: I will take Ceresota. Then a bag of salt—just a little bag. Three cans of Pet milk—large cans. How much are they?

Clerk: A quarter.

Woman: How much is pound tea?

Clerk: Eighty-five cents.

Woman: And half a pound is 43 cents. (*A half pound of Lipton's is put with her order by the clerk.*) All right, figure that up.

Clerk: Have you got butter, bread, eggs?

Woman: Well, I'll come out again.

Clerk: That's \$1.02.

And so on throughout the day.

What Kinds of Information Can Be Secured from the Retailer? A definition of primary kinds of information that can be secured from the retailer is offered as follows:

Trade Brand Recognition, Acceptance, or Preference

Definition. The kinds of products sold by the retailer under brand name, the brands carried by the dealer, and the degree of recognition, acceptance, or preference which the product studied, as well as any competing product, enjoys.

Sample questions:¹

1. To what extent is the type of product studied sold under brand name?
2. Competing brands carried by the dealer?
3. What brands occupy a major position in the retailer's mind?

Sales Volume

Definition. The amount of the product together with the amount of each competing product sold by the retailer.

Sample questions:

1. How many units of the product, and of each competing product, does the retailer sell in a week, a month, or a year?
2. What proportion of the product and of each competing product is sold at "special" prices?
3. What is the rate of turnover for the product among various classifications and types of retailers?

Advertising Media

Definition. Most effective media used by the company and by competitors in influencing the retailer.

Sample questions:

1. What method of store advertising seems to be most effective in influencing the retailer? (Store demonstrations, window displays, inside-store and counter displays, premium sales, etc.)
2. What media reach the retailer? (Trade papers, direct mail, radio, house organs, etc.)
3. Which consumer advertising media seem to influence retailers most favorably?

¹ These sample questions should be read as possible topics to be covered, not as direct questions to be used, in interviewing retailers.

Effects of Merchandising and Sales Service

Definition. Effects of the merchandising and sales service of the company and of competitors upon the retailer.

Sample questions:

1. What is the attitude of dealers toward the price, merchandising, and sales service offered by the company and by competitors?
2. Is there any feature of the retailer cooperative service offered by the company which is superior to competitors' service and which has effected good-will for the company?
3. Is there any feature of the retailer service offered by the company which is inferior to competitors' service and which has caused ill will for the company?

Trade Buying Habits

Definition. When, where, how often, in what quantities the retailer buys the product.

Sample questions:

1. How much of the product do different classes of retailers buy at one time?
2. To what extent can the time, frequency, or amount of purchase be influenced?
3. To what extent are retailers buying special deals from competitors?

Interviewing the Retailer. Even though the retailer is satisfied that the investigator is not trying to sell anything, he is still likely to be hedgy about giving out information.

But the hedgy retailer can sometimes be transformed into a most willing subject if the investigator will spend a few minutes, in the beginning, to tell him "all about" the survey. It is not difficult to compose a brief explanation that will get the retailer's interest. Once this interest is secured, the investigator must be very careful not to disturb it. Note taking during the interview usually causes the dealer to become more hedgy and less specific. The investigator should have the entire interview so well organized in his own mind that he is easily able, without taking notes, to retain the information at least until he has left the store, when he may record the interview in detail.

Do Not Expect the Retailer to Be a Statistician. When we consider that most retailers carry hundreds of different items on their shelves, it is easy to understand why they are seldom able to give offhand close estimates on the amount of sales, or in some instances, even a dependable statement of the rank of a given product as compared with the sales or rank of competing goods, unless the product being studied is an outstanding leader or an exclusive sales item.

The dealer is often incompetent to answer a question simply because the answer involves mental calculations. If a question is asked in such a way that the dealer is relieved of this mental arithmetic, he can often give the raw facts from which the interviewer may calculate the answer. Retailers are notably incompetent to estimate percentages. Take a simple illustration. Suppose one wants to know the approximate percentage of business enjoyed

by X brand canned milk in a certain store. Instead of asking a dealer what per cent of canned milk sold is X brand, it might be better to ask, "How long does a case of X brand milk last you?" and then ask, "About how long does a case of Y brand last you?" Y, of course, is the competing brand to be compared. The investigator will know the *number* of cans and the *size* of the cans packed in a case of each brand, and after getting the approximate length of time a case of each lasts, he can easily calculate the approximate percentage of business enjoyed by each brand in that store. The important thing to note in this plan of questioning is that the investigator associates the answer to his question with a common dealer operation of opening or ordering a case of canned milk—an operation likely to be recalled easily by the retailer.

Getting Information from the Jobber

What Kinds of Information Can Be Secured from the Jobber? The use of the jobber as a source of information is largely restricted to possible information that he might be able to give concerning various types of retail outlets with which he deals, and his general attitude toward the merchandising, sales policies, and service of the company. Sometimes a jobber is able to give helpful information about the relative sales of competing products, but one should not expect the jobber to give any information about competitors that might be considered confidential. Because his sales records are seldom kept in a way that makes easy the tracing of shipments on an individual product, the jobber typically is not in position to give out ready information concerning rates of shipments of a product to various retail outlets.

Getting Lists of Retailers from the Jobber. A New England clock manufacturer, selling through jobbers and introducing a new clock, wanted the names of the retailers who handled his clocks so that he could use them as a source of market information. The jobbers, quite naturally, did not want to give the names of the retailers.

This clock company handled the problem by giving a ten-year guarantee with each clock. In order that the guarantee be effective, the purchase record had to be signed by the customer and dealer and returned to the general office. By this system, the names of actual users and dealers came in automatically.

The Standard Textile Products Company¹ wanted a list of painters and decorators to whom jobbers of Sanitas were selling the product, so that the company might distribute sample books directly to these painters and decorators and encourage the sale of the full line of patterns. When asked for their customer lists, the jobbers offered the following objections:

1. We would not trust anybody with our list of customers. We have tried that out with other manufacturers whose employees betrayed our confidence.
2. As we do not carry the full line, how are we going to execute orders for styles we do not carry in stock?
3. We prefer to send out sample books showing the styles we carry and have our name on the cover as we always have.
4. We want time to think it over; it does not sound practical.

¹ BEHRENS, J. WARREN, "How Sanitas Obtained Valuable Customer Lists from Wholesalers," *Printers' Ink Monthly*, March, 1928.

The company was able to meet these objections in a sufficient number of cases to secure customer lists from almost 50 per cent of its jobbers. Whenever a painter or decorator writes the Standard Textile Products Company, that inquiry is referred back to the jobber who furnished the name of the painter or decorator. And so the manufacturer gives evidence of his good faith with, and support of, the jobber.

Jobber Prejudices. Special interests of the jobber may interfere with a satisfactory interview unless they are taken into account by the investigator. In the first place, the jobber's interests largely revolve about those products for which he has an exclusive agency. Second, he is typically prejudiced in favor of those products which represent his most profitable accounts. Third, he often pushes his own private brands, and some statements made by him concerning these brands may have to be discounted.

Means for Gathering Market Information

The foregoing discussion implies the exclusive use of skilled investigators as a means for gathering information. There are, of course, other means such as unskilled investigators, company salesmen, and the mail questionnaire. But those who have had extensive experience in the study of markets would probably agree that one cannot hope to secure anything like an adequate picture of the marketing situation without the use of skilled investigators.

There are, of course, exceptional instances in which unskilled investigators may be used when the information to be secured is neither subtle nor difficult to get. In the periodic collection of standardized data, company salesmen may sometimes be used providing the data secured do not in any way involve the interests or the abilities of the salesmen.

Difficulties in Using the Mail Questionnaire. As far as the mail questionnaire is concerned, the following difficulties are encountered:

1. Only a relatively small percentage of questionnaires are returned, and those people who do not answer often have the information most useful to the marketing executive.

2. It is difficult in most cases to control the distribution of replies so that all important classes of people and geographical territories are adequately represented.

An experimental study¹ which illustrates a case of distorted market information is offered as follows:

A special house-to-house advertising program covering a number of cities had just been completed. In attempting to measure some of the results, a mail questionnaire was sent to a group of housewives in each city where the work was done. The percentage of questionnaires answered was high and the distribution of replies was good. The data were tabulated.

At this point most mail studies stop. Those who secure information by mail are usually well satisfied if 30 per cent or 40 per cent answer and if the replies are well distributed geographically. But even with these two requirements satisfied, three important questions remain unanswered.

¹ REILLY, WILLIAM J., "Checking up on Data Secured by Mail Questionnaires," *Printers' Ink*, p. 71, Dec. 23, 1926.

1. Who answered the mail questionnaire?
2. Who did not answer the mail questionnaire?
3. How accurate is the information given by those who did answer the questionnaire?

To sense the importance of the first two questions, it is only necessary to recall that the percentage of mail questionnaires answered is seldom as high as 50 per cent. In other words, over half of the people to whom the questionnaire is sent are not heard from.

The significance of the third question is obvious, for if the information given by those who do answer is inaccurate, it may become practically useless, depending upon the degree of inaccuracy.

In order to discover who answered our questionnaire and who failed to answer it, as well as to learn how accurate was the information given by those who did answer, we set out to get the facts, using the following method:

1. Copies were saved of the names and addresses of all persons to whom the mail questionnaire was sent.
2. Three of the cities in which the mail questionnaire was used were selected for the purpose of sample study.
3. Personal interviews were secured with those who had answered the mail questionnaire and what they answered in personal interview was compared with what they answered by mail. These personal interviews were so planned that the housewife did not feel conscious that the accuracy of her answers by mail was being questioned.
4. Personal interviews were secured with those who had not answered the mail questionnaire, in an attempt to discover what kind of people did not respond.

The more significant results of this investigation are as follows:

1. Of the housewives who answered the mail questionnaire, 92 per cent were found to be users of our product and only 8 per cent were non-users.
2. Of those housewives who did not answer our questionnaire, 40 per cent were found to be users of our product and 60 per cent were non-users.
3. Those who did answer the questionnaire gave information that was exceptionally accurate; in fact, only 15 per cent of the answers given in the mail questionnaire differed from those received in personal interviews, and the differences were so divided between favorable ones and unfavorable ones that they resulted in a balanced error which did not appreciably disturb results.

Because the information by mail was received almost entirely from regular users of the product, it was highly favorable and gave a distorted picture of the market as a whole. Furthermore, the mail information did not include useful suggestions such as were received in personal interview from non-users who had objections to the product.

IV. KEEPING IN CONTINUAL TOUCH WITH MAJOR FACTORS

A company's marketing situation is subject to continual change, and one must therefore provide for a periodic check-up on the behavior of factors which dominate that situation.

Keeping in Continual Touch with a Potential Market Factor. An automobile accessory manufacturer found, in studying the production figures in the automobile industry, that his sales were not increasing so fast as the total

production of automobiles. In attempting to get at some explanation, he separated the production figures into two groups. In group 1 he included the more expensive automobiles for which type A of his product was made;

FIG. 3.—Unit sales of an automobile accessory compared with passenger-car production (United States and Canada 1913 to 1929).

in group 2 he included the less expensive automobiles for which type X was made. This analysis revealed that the sales of type A (made for more expensive automobiles) were keeping in step with the production of higher-priced

cars, but that the sales of type X (made for cheaper automobiles) were not increasing nearly so fast as the production of lower-priced cars. A field study showed that type A was much more acceptable to owners of expensive cars than type X was to owners of cheaper cars, and that competitors, with a lower-priced product, were getting the mass business among owners of lower-priced cars.

The manufacturer decided, therefore, to put out a new grade of his type X product in a lower-price range for owners of cheaper cars. Fig. 3 indicates the behavior of this manufacturer's sales in relation to automobile production, prior to and since 1923 when the change was made.

Keeping in Continual Touch with a Price Factor. The sale of a grocery product, let us call it Alto, slumped and the most important consumer

FIG. 4.—Price difference compared with sales increase or decrease.

objection was that "the price is too high." What did consumers mean? "Too high" for what? Did they object that Alto cost 50 cents? Not exactly. They *really* meant that they did not like to pay 50 cents when they could get another brand that served their purpose as well, or almost as well, for 35 cents. In other words, it was the *price difference* between Alto and competing brands to which housewives objected.

After examining the past sales of Alto and the price variation of Alto in comparison with competing brands, over a period of years, the manufacturer found (1) when the difference between the price of Alto and the price of competing brands was greatest, the sale of Alto suffered most, and (2) when the difference between the price of Alto and the price of competing brands was least, Alto enjoyed its largest gain in sales (see Fig. 4).

The final step in this study was to discover that point at which the price difference between Alto and competing brands became critical, *i.e.*, that point beyond which the price difference could not go if a satisfactory increase in volume was to be expected.

Thereafter, the company's level price policy was discarded and the price to the dealer was raised or lowered so that in turn the price to the consumer could keep in step with the critical price difference. Under this plan the *average* price received by the manufacturer for Alto over a period of years has been higher than it would have been under the old level price policy, and sales have experienced a more consistent and satisfactory rate of increase.

Keeping in Continual Touch with a Style Factor. A projected study for the manufacturer of a style product includes a periodic record of his sales in a number of retail stores in selected locations and a comparison of the sales

FIG. 5.—A comparison of design A's production and sales in selected locations.

of various designs with his production schedule on each design. Fig. 5, for example, shows that the company started out in January with a schedule providing for 10 per cent of its production assigned to design A. A check-up on retail sales in selected locations during the month of January revealed that design A was responsible for only 4 per cent of the total sales of the company in these retail outlets. The production schedule, therefore, was revised on February first so that only 5 per cent of production was assigned to design A.

A periodic check-up of retail sales during February, March, April, May, and June showed that design A was steadily declining in popularity. The production schedule on this design, therefore, was adjusted during these

months as is indicated in Fig. 5. Interviews with retailers during the month of June showed that they were so dissatisfied with excess stocks of design A and were so doubtful that they would be able to get rid of these stocks, that the company decided to discontinue production on design A, to give a special allowance on this particular design, and to encourage retailers to reduce their prices and to hold special sales during July.

Keeping in Touch with the Changing Consumer. All of us can recall instances where companies have interviewed (1) former customers to discover why their business was lost, (2) present customers to keep in touch with the performance or use of the product, and (3) users of competing products to find out why those competing goods were preferred. And it is extremely important to keep in touch with these groups. But markets are always on the march and ordinarily the potential customers with the longest life are the newcomers in the market. Furthermore, a manufacturer may encounter less opposition in getting business among these newcomers where buying habits are not yet molded and where prejudices are not yet established. Every market has its newcomers and it is wise for any manufacturer to keep in touch with the requirements of this new section of his market and to attempt to influence buying habits and prejudices which are in the making.

For example, excerpts from one periodic survey of the newlywed market, conducted for the general purpose of keeping in touch with the food problems of newlyweds and for the more specific purpose of observing their coffee-buying habits in the making, are offered as follows:

Newlywed Market¹

1. *Dimensions of the Newlywed Market.* The following table gives some idea of the dimensions of the newlywed market in the United States:

Year	Number of Marriages
1925	1,188,334
1926	1,202,574
1927	1,201,053
1928	1,182,497
1929	1,232,559

In other words, these five years have seen the advent of over 6,000,000 new purchasing agents into the food markets of the United States.

2. *What Are the Newlyweds' Biggest Food Problems?* According to the interviews secured, the biggest food problem of the newlywed housewife is *planning the meals*, so as to get a variety in the menu. Other important problems mentioned are knowing how much food to buy and prepare, recognizing quality, buying economically, and getting the right balance in food values.

3. *Previous Experience of Newlyweds in Buying and Preparing Food.* Fifty per cent of the newlyweds interviewed said that they had had practically no experience in buying or preparing food before they were married.

4. *Sources of Help on Food Problems.* When asked where they received most of their help on food problems, 64 per cent of the newlyweds interviewed said that they got considerable help from cook books. Some of the cook

¹ Newlyweds are defined as those who have been married less than two years.

books mentioned are published by manufacturers and others by independent food authorities. Fifty-five per cent said that they got help from their mothers. Forty-four per cent mentioned magazines as a source of help; 28 per cent mentioned friends; 26 per cent mentioned newspapers.

5. *Do Newlyweds Do Their Own Cooking?* This study was conducted among classes of people with moderate incomes ranging somewhere between \$1,500 and \$5,000 per year. Eighty-five per cent said they did their own cooking; 8 per cent did part of their own cooking, and the remaining 7 per cent said they did not do any of their own cooking.

Seventy-five per cent said that they liked to cook; 15 per cent said that they did not; 10 per cent seemed indifferent toward cooking.

6. *Where Does the Newlywed Buy Her Food?* There was a slight preference for the chain stores, among the newlyweds interviewed; 26 per cent said they did most of their buying at the chain stores; 24 per cent said they did most of their buying at independent grocers; 26 per cent said they shopped at both; and 4 per cent said they bought most of their food at cash-and-carry public markets. The remaining 20 per cent were divided among combinations of these three types of outlet.

Of those housewives who shop at chain grocery stores, 65 per cent mentioned "price" and 32 per cent mentioned "close to home" as a reason for doing so. Other important reasons given were "quality" and "variety."

Of those housewives who shop at independent grocers, 30 per cent mentioned "close to home," 21 per cent mentioned "quality," and 16 per cent mentioned "delivery service" as their reasons for doing so. Other important reasons given were "reliability," "personal interest," and "service."

7. *Coffee-buying Habits of the Newlywed.* Forty-nine per cent of the newlyweds interviewed said that they were influenced by their mothers' advice in selecting their first brand of coffee; 26 per cent said that they were influenced by advertising; 14 per cent said they were influenced by friends. Other influences mentioned were "mother-in-law," "dealer influence," "price," "blind choice," and "the package." In many cases, of course, more than one of these influences were mentioned as having some effect on the selection of their first brand of coffee.

Fifty-six per cent of the newlyweds interviewed still use the brand of coffee with which they started and 42 per cent have changed brands.

Of those housewives who changed brands of coffee, 38 per cent said they did so because they tired of, or became dissatisfied with, the first brand; 24 per cent gave "price" as a reason for changing brands. Other important reasons given were "friends' influence," "advertising," and "dealer influence."

Sales Territories Should Permit Comparison of Sales Results with Market Possibilities and Marketing Costs. But after all, the marketing manager cannot hope to keep in continual touch with the total effects of dominating factors unless he has some system of sales territories which permits safe periodic comparisons of sales results with market possibilities and marketing costs.

Without such a dependable running record of what is happening in various territories, he has no safe basis for determining where sales are good or where they are bad, and he has little chance to send his representative into unsatisfactory territories and to discover, before it is too late, what factors are responsible.

That manufacturers should organize their market records on the basis of trade territories rather than on the state basis is a principle that has been expressed over and over again in marketing literature. And in recent years a

number of helpful maps have been prepared to indicate roughly the dimensions of such retail-trade territories. But marketing managers have come to realize that no set of maps can safely be applied to all products. Meanwhile, lack of information about the *underlying rules* that govern the flow of retail trade¹ for *different products* has made it extremely difficult for anyone to devise a plan that will satisfy the peculiar requirements of each individual manufacturer.

The marketing manager does not need a set of general maps; he needs method that will help him to build up his own sales territories. He does not need some standardized plan devised on the outside and all ready to be superimposed upon his business; he needs method that will show him how to start with the experiences, aims, and conditions of his own company and to set up territories that will fit his own peculiar requirements. In attempting to use various standardized plans (all of which are different), he has failed so consistently to arrive at a satisfactory solution (because there is no such simple solution) that he is on the verge of losing confidence in the possibility of setting up dependable sales territories. But he is also prepared, after such disappointing experiences, to accept any method that he feels will help him to work out an individual solution to his own problem.

Into How Many Territories Should a Manufacturer Divide His Sales Map? The first question encountered in attempting to set up sales territories for an individual manufacturer with national distribution, is "Into how many territories should this manufacturer divide the United States?" The number of territories depends upon such factors as the product, consumer buying habits in relation to that product, the manufacturer's methods of distribution and market programs in various parts of the country, the amount of money which the manufacturer wishes to appropriate for such record keeping. It is conceivable that one hundred manufacturers of similar products may set up their territories in one hundred different ways.

In conclusion, there is no contention that a manufacturer cannot get along without a systematic plan for market analysis. Manufacturers are doing it.

The early steam engine could pull a train, but it used a lot of coal. Of course, the more efficient the engine, the more economically it can be run, and the more efficient the marketing organization, the more profitably it can be operated.

But meanwhile one can still run an inefficient engine if he has enough coal and one can continue to run an inefficient marketing organization if he has enough money. And that's just where the waste comes in.

CHAPTER II

ADVERTISING¹

BY WILLIAM J. REILLY, *The William J. Reilly Company*

The word "advertising" has come to be associated primarily with the use of the commonly talked-of media such as magazines, newspapers, outdoor displays, radio. This association is unfortunate for a true definition of advertising implies no such restrictions. The Latin *advertere* means "to turn to," and "to advertise" a product or a service means to turn people toward it.

No manufacturer is interested in advertising *per se*. He is interested in its use only as a possible means for realizing his business objectives. In striving to attain these objectives, he has at his disposal a number of marketing instruments which he may want to consider in the light of their effect on his total business situation. One of these marketing instruments is advertising.

The major questions that any manufacturer faces in relation to advertising, then, are:

1. Considering my total business situation, can advertising be profitably used?
2. If so, what advertising media or methods are best adapted to my needs?

I. THE TOTAL SITUATION APPROACH TO ADVERTISING

Until recently we have been thinking of the manufacturer's total business situation as comprising two main jobs; first, production and, second, distribution. And the manufacturer could think that way with little risk at a time when he needed only to make a product according to his own ideas and then distribute it to a virgin and uncritical market.

But now that markets have become cultivated and competitive, that consumers have become discriminating, and that production has begun to catch up with, and in some cases surpass, the requirements of consumption, it has become necessary for us to change our order of thinking. We must now begin by consulting the consumer. Not until we know what the consumer wants is it possible to reduce to a minimum the speculative factors in production.

Even after the goods are produced, we can no longer use the word "distribution" to describe adequately the kind of job faced in attempting to market goods. Many are competing for the consumer dollar and if any manufacturer

¹ This brief treatment of a large subject is prepared not for the advertising technician but rather for the business man who may want to consider the use of advertising.

is to get his coveted share of the business he must devise methods for influencing and controlling the consumption of his particular product.

As a result of these recent changes, any redefinition of the manufacturer's job might well include three main functions:

1. To study the market for his particular product and to find out what kind of product the consumer wants or will want when told about it.
2. To produce that kind of product.
3. To market his product—guided by continuing market studies that help him to influence and control the consumption of that product.

Some of these points are not new. In fact, they have been much discussed within the past few years. But they have not yet found their way into general practice. Manufacturers have been so used to thinking "production and distribution" that it is still quite common for them to make a product on the assumption that there are good reasons why consumers should want it. How much sounder it is to find out first what the consumer wants, or can be made

FIG. 1.—Various phases of the total business situation the costs of which may be affected by advertising.

to want, and how much easier to write effective advertising copy if a product is designed from consumer specifications. Furthermore, if consumer wants are discovered first, the product itself is more likely to measure up to what advertising would like to claim for it.

Whatever place advertising has in the total business situation, it is connected with the job of influencing or controlling consumption—and, as we shall see, even then advertising is only one of a number of marketing instruments that might be used to gain such influence or control.

However, before we discuss the use of advertising, or the use of any other instrument, to stimulate a business, we should arrive at some understanding of the effects that such a stimulus might have upon the total business situation at various stages in the development of a business. (See Fig. 1.)

Effects of Volume Increases. One idea often accepted without sufficient question is the popular belief that any business stimulus, that increases volume, automatically effects economies all along the line from the purchase

of raw materials to the final distribution of goods. And so it is frequently claimed that, whenever advertising increases volume, economies invariably follow. But this notion should not be too readily approved as applicable to all cases.

It is scarcely necessary to emphasize that there may be, in the case of any individual manufacturer, many ways of getting an increase in volume; and that the source and the nature of volume increase has much to do with the effects that such increase will have upon various costs of production and marketing and consequently upon profits.

Seeking Profitable Increases in Volume. Any manufacturer is interested in discovering what periods, what products, and what territories promise the most profitable increases.

In the first place, a study of production costs may show that an increase during peak months of the year or peak years in the business cycle would require additions to plant and machinery—additions that would really intensify his problem of unused capacity during off-peak seasons—while any increase in trough months of the year or in times of business depression would be very profitable indeed.

In the second place, a study of the present and potential market, the trend in the market, and the unit profit on each of his products, should clearly indicate which one or more of these products deserve to be pushed.

Third, an analysis of the costs of doing business, the competitive resistances, and the size of the market in each territory should help him to select, for special development, those territories which offer the most promising possibilities.

A Method for Recording Effects of Volume Increase on Costs and Profits. Method is usually about as popular as the neighbor's dog. It is likely to get kicked out without a hearing. We are quite anxious to throw aside, as unimportant, any method with which we are not familiar and the common reason for doing so is: My case is different. But after we become familiar with a method, we begin to realize its importance and to see that the method can be applied to a wide variety of cases. Even before our first grade in school we knew that two apples and two apples were four apples. But when we were first taught that thirteen plus twenty-six equals thirty-nine, it was difficult for us to see the importance of learning that. We wanted to know: thirty-nine what? Only after we became thoroughly familiar with methods for addition did we begin to understand that thirteen plus twenty-six equals thirty-nine of anything—that methods for addition have nothing to do with subject matter.

Similarly, the suggested plan which we are about to offer is merely a method for arriving at profits and for presenting this situation in graphic form so that it can be easily grasped. Any manufacturer can apply this method to his own business regardless of the nature of the items that he includes in his budget and regardless of the manner of their increase or decrease at different periods in the volume development of his business.

The case of John A. Manufacturer will be used merely to demonstrate the method for recording the effects of increasing volumes upon costs and profits.

John A. Manufacturer's Production Costs. John A.'s production costs are charted in Fig. 2. When his business was small he had only one

battery of machines and, as he gradually attained a sales volume that permitted him to run this battery of machines at full capacity, his unit production costs gradually declined from 50 to 40 cents. But a slight additional volume made it necessary for him to add another battery of machines. Each abrupt vertical rise at the left of the production curve indicates a point at which he added a new battery. We see on the chart that these sharp increases in unit costs became smaller with the addition of each group of machines. For although the actual amount of money involved in each battery was approximately the same, the expense of each addition to machinery became smaller in relation to the entire production cost as the number of machines increased, until finally the expense of adding another was such a small part of the whole production cost that the fluctuations in the curve resulting from such additions disappear on a graph of this scale.

The gradual decline in John A.'s unit production costs in the later stages of rising volumes was largely due to (1) his increasing purchasing power which enabled him to buy raw materials at lower prices, (2) the stabilization of his

FIG. 2.—Production cost per unit.

production schedules which permitted lower labor turnover, (3) the standardization of his product which reduced his costs of planning and design, and (4) the economies effected by an efficiency supervisor who reclaimed and reused materials that had previously been wasted and who also made a number of reductions in overhead items.

John A.'s Marketing Costs. Now let us look at John A.'s curve of marketing costs (see Fig. 3). In the very early stages of his business he sold all of his product to those who called at his place of business and to retail outlets within a few miles. His delivery costs were very low. He had no sales force; no advertising appropriation. Then he attempted to build his volume by extending operations into new territories. Now for the first time he needed a sales force. He included an advertising appropriation in his budget. His delivery costs increased. His total marketing costs rose sharply to point A.

As he developed these new territories, economies in larger scale transportation, an increasing number of productive calls per day by salesmen, and lower

unit costs of advertising through the use of mass media whose circulations were coextensive with these new territories, were the main contributors to a reduction in marketing costs per unit to point *B*.

At the next stage of his business, John A. decided to open up a second group of territories. Because of the increase in sales force, advertising appropriation, delivery costs, and sales supervision, his total marketing costs went up to point *C*. But he found that four of these new territories were very rich and productive ones because (1) the population was increasing very fast, (2) competitors had not so thoroughly established themselves as they had in his former territories, and (3) the climatic conditions caused consumers to use the product in much larger quantities. The net result was that his marketing costs in these four territories were so low that the unit costs of marketing for his entire business declined to point *D*—lower than it had ever been since he began to open up new territories.

FIG. 3.—Marketing cost per unit.

John A. then began to feel that certain marketing economies could be effected if he would further extend the distribution of his product to cover the entire United States. This extension caused an immediate rise in marketing costs per unit to point *E* on the graph. These last territories to be opened up were not quite so fertile as some of the previous ones. He realized some decreasing costs, as these last territories were developed, but it took some time for the economies in his national marketing program to effect a reduction in unit costs. Gradually, however, he began to enjoy more effective cooperation of retailers and jobbers, to increase efficiency in the national sales organization, to make more resultful use of national advertising media, and to secure a higher turnover on his product, all of which contributed to a decline in marketing costs per unit to point *F*.

John A. was so encouraged that he went after still greater volume. His experience with advertising had been extremely favorable. Every time he

had increased appropriations, his volume grew. He now decided to increase advertising expenditures more than ever. He used house-to-house sampling. He increased his space in national magazines. He initiated local newspaper advertising, store demonstrations, and special premium sales among retailers.

Rising Marketing Costs and Declining Profits. Before long he began to realize that his marketing costs per unit had risen sharply to point G, that his profits were dwindling, that he was getting lots of volume but was not making much money. By charting his costs and profits as shown in Fig.

FIG. 4.—Price, cost, and profit per unit.

4, John A. found that when he increased his volume from 6,000,000 to 7,000,000 units, his profit per unit began to decline.

A Study of Costs from the Inside Out. In Fig. 4 the total cost curve is secured by adding production costs to marketing costs. The curve showing the price which John A. received for his product is explained as follows. When he operated locally he sold his product for \$1.10. When he decided to expand his territory he was forced to raise the price of his product to \$1.20 where it remained until his market had been expanded to a national scale and he found that competition with other products obliged him, and decreasing

total costs permitted him, to reduce the unit price of his product to \$1.00. The curve showing John A.'s net profits per unit at various stages in the development of volume is secured by subtracting total cost per unit from the unit price received. This net profit curve shows wide fluctuations in the early stages of volume resulting from the wide fluctuations in costs of production and marketing. After he began to distribute his product on a national basis, his net profits per unit gradually rose with decreasing costs per unit until that point was reached in the development of volume where the resistance of the market began to narrow the profit margin.

Companion Fig. 5 (derived by multiplying the number of units sold by the net profit per unit) shows John A.'s volume of profit at various stages in

FIG. 5.—Total net profits.

the development of sales volume. It is evident that he enjoyed the largest volume of net profit when 6,000,000 units were reached.

A Study of Causes from the Outside In. John A. then studied his business further. He initiated a field investigation. He discovered that one of his competitors was imitating his advertising methods; that he was getting new business from this competitor who, in turn, was following up with similar methods and taking some business away from John A. It was clear that he and his competitor were spending a lot of money exchanging business, but neither was really getting anywhere. John A. had started the whole thing. He had reason to believe that his competitor would stop this extensive raiding if he would, so he decided to "stay in his own backyard." He realized, a little late to be sure, that the 6,000,000-unit mark was, for the time being at least, the volume on which he could make the greatest profit.

This case of John A. Manufacturer is sufficient to demonstrate that the stimulation of any business should be studied in relation to the total business situation, that various cost and income items are dynamic in their behavior, that profits are vitally affected by changing relations among these items with the growth in volume, and that it is necessary to keep in continual touch with these changing relations.

After anticipating some of the more important effects that volume increases from various sources might have upon his costs and profits, any manufacturer is in a more intelligent position to determine what kind of increase promises to be profitable and to consider what marketing instruments might best be employed to secure that increase.

Considering Various Marketing Instruments. In attempting to secure profitable increases, the manufacturer has at his disposal five main marketing instruments:

1. The product itself.
2. The availability of the product.
3. The price of the product.
4. Advertising.
5. Personal selling.

To begin with, let us avoid any possible impression that the stimulation of a business necessarily involves the use of only one or two marketing instruments. In any given case, all are likely to be involved, but with varying degrees of emphasis. There are those close to advertising who in their approach to this problem are likely to be too easily persuaded that advertising is the dominating force in most market situations. As we shall see this is not so often the case. The cases which follow will at least intimate the type of situation that requires primary emphasis upon each of the various marketing instruments available.

The Product Itself. There are a number of situations in which the product itself deserves primary emphasis in attempting to stimulate a business.

A manufacturer of a machine for factory use found in interviewing superintendents of factories where his machines were discontinued, that they had been replaced by those of a competitor because the competitor's machine was equipped with a device for saving part of the raw material which previously went to waste. This information led the manufacturer to add this device to his machine.

Another manufacturer found that he could produce staple goods in off-peak periods. In this case, staple merchandise was an important instrument in gaining new volume.

There are numerous cases where a manufacturer has stimulated his business merely by changing the packaging of his product. For example, a manufacturer of a beverage secured a substantial increase in sales by modernizing the appearance of his bottle and changing its shape. He also reduced its height to that of an ordinary milk bottle so that it could more conveniently be put into an icebox in an upright position.

A cooperative association of raisin growers stimulated their business by adding a small-sized package.

Such package and size advantages, however, are usually temporary. Soon after one manufacturer makes an important change in packaging,

competitors usually adopt a similar improvement. As a rule no one company possesses a monopoly on brains or patent privileges. The manufacturer, therefore, finds it increasingly difficult to maintain exclusive advantages in the product itself and in recent years he has been forced more and more to consider the use of other marketing instruments as a basis for whatever advantages he may hope to secure.

Availability of the Product. It is commonly agreed that the sale of any product is influenced by its degree of availability. But there are situations in which availability may be the dominant marketing instrument in increasing sales. For instance, availability alone may greatly influence the sale of a product for which there is an elastic demand—a product like apples. Then, too, in selling X brand of gasoline (which is one of a group of readily acceptable brands) primary emphasis was found to rest upon the distribution of pumps rather than upon price, product, advertising, or personal selling.

A manufacturer of a drug specialty increased his volume merely by making his product available in self-service grocery stores. It is easy to recall many recent cases where volume increases have been secured by extending the distribution of products into new types of outlets or into better located outlets.

Price of the Product. While price is one of the marketing instruments that might be employed to stimulate a business, yet its use must be approached with extraordinary caution. It is easy enough to reduce prices to meet a temporary situation, but it may be very difficult later to bring them back to a satisfactory level. The use of price concessions is more likely to involve unanticipated and unwelcome developments than the use of any other single marketing instrument.

All of us can think of examples in which price has been used to meet a market situation. It is not uncommon for competitors to offer larger discounts and allowances and for a manufacturer to meet competitive terms. There are many instances where manufacturers have reduced their price on the presumption that they would secure a sufficient additional volume to compensate the reduction.

Only the exceptional manufacturer can hope to enjoy sustained "cost" advantages over competitors. Yet price¹ can sometimes be used in skilled hands as a strategic marketing instrument for increasing profits. Any example, however, that might be offered in relation to the use of price as an instrument would necessarily involve a prolonged discussion of far-reaching implications—the kind of discussion that is not permitted in the brief reference to price that is made in this treatment.

Advertising and Personal Selling. The fewer market advantages a manufacturer enjoys in relation to the product itself, the availability of the product, or to its price, the more emphasis he needs to place upon advertising or personal selling, or both, in attempting to sell his product. Advertising and personal selling are so closely related in function that the consideration of one usually involves the other. Although the function of both is to inform and

¹ After all, the price of a product may not be nearly so significant as the difference between the price of that product and the price of competing products (see Chap. I, pp. 32-33).

persuade so as to turn people toward a product, one cannot generalize about the extent to which either carries this persuasion toward the point of sale. There are extreme cases where either one or the other seems to do almost all of the work.

It is possible, however, to make one distinction between the two on the basis of method that is employed. Some may find it helpful to think of advertising as including all mass media or methods for communicating a given message to a large number of people, in contrast with personal selling which might be thought of as including any method designed to give each person individual attention by adapting the description or suggested use of the product to that person's special requirements.

How personal selling should supplement advertising under different circumstances is sometimes difficult to determine. True, there are clear-cut cases at both extremes. One manufacturer of steam shovels, for instance, places primary emphasis upon personal salesmanship. Advertising is used incidentally, merely to add prestige to the steam shovel salesman's calling card. On the other hand, a manufacturer of chewing gum, who distributes solely through jobbers and large retail organizations, places primary emphasis upon advertising. Whatever personal selling he employs is incidental.

Between these two extremes, however, are many products—not so easily classified.

A maker of mayonnaise dressing, because of the perishable nature of his product, has salesmen who periodically make a check-up among retailers. These salesmen are on a "Bill" and "Joe" basis with the retailer and personal service shares emphasis with consumer advertising.

The method for distributing a given product may have some bearing on whether the emphasis belongs on advertising or on personal selling. For example, one manufacturer of corn flakes, who sells his product in bulk to jobbers who, in turn, sell it under their own private brand, emphasizes personal selling, while another manufacturer of corn flakes, who packages and sells his product under his own brand name, emphasizes advertising.

The manner of selling the product to the consumer sometimes affects the relative emphasis upon advertising or selling. A manufacturer of household paint knows that a hardware merchant may be able to sell any one of a number of fairly well-known paints, providing he builds up a reputation for good advice on how to paint a breakfast room set or the kitchen wall or a second-hand automobile. This manufacturer, therefore, divides emphasis between personal selling to the retailer and consumer advertising.

A manufacturer of a machine part, realizing that his patents would soon expire, faced the problem of maintaining a hold on the business. He considered the possibility of reducing prices so that others might be discouraged from entering this business in competition with him. He found that, on the basis of his present volume, a price reduction (that would be of any consequence to the consumer) would reduce his income approximately a million dollars, and that the prospects of securing sufficient additional volume to compensate such a price reduction were not at all promising. Driven to another strategy, he elected, as an alternative, to maintain his price and to spend one-half million dollars in advertising. The net result was that, when

his patents expired, he had gained such a firmly entrenched priority in the field, that only one manufacturer attempted to compete with him. And this competitor found the market resistance so great that he met with very little success.

It would be a mistake for anyone to infer, however, that there are set rules to be followed in emphasizing various instruments or that any given marketing situation can be solved in only one way. In actual practice most cases are neither at one extreme nor at the other and there are any number of possible solutions, involving different combinations of advertising and selling, and involving a wide variety of emphasis on the use of other marketing instruments.

Brief as this reference to various marketing instruments has been, it should be sufficient to show that the intelligent use of advertising involves a thorough, fair-minded appraisal of all other marketing instruments.

This total situation approach to advertising, involving the study of profitable increases and the consideration of various marketing instruments, seems at first sight to be unduly complicated. But in actual practice, most of the information essential for the studying of these problems, can ordinarily be secured from a company's files, from trade associations, and from other readily available sources of information.

In any case, of course, the essentials should be secured however difficult they may be to get; the non-essentials are not wanted however easy they may be to get. Unfortunately, an ambitious but misdirected analyzer may spend an immense amount of time digging into phases of the business and getting large quantities of data that have no immediate connection with practical decisions to be made. And the more these non-essentials are elaborated, the more the essentials are clouded. This total situation approach to advertising, then, has for its main requirement an analyzer who has a sharp nose for essentials.

II. DEFINING THE ADVERTISING JOB

Whenever a manufacturer finds that advertising has a place in his marketing program, he immediately faces the necessity of defining the advertising job to be done, somewhat as follows:

1. What are the primary and secondary objectives of his advertising?
2. Whom does he want to influence?
3. What does he want to tell them?
4. What time limits are involved?
5. Which media should be used?
6. How much money is required?

The need for defining the advertising job is so extremely obvious that one is likely either to take for granted that he knows what he wants to do without going to the trouble of defining it, or to arrive at a hasty definition on the basis of assumed rather than known conditions.

Ordinarily, there is too much premature thinking about appropriations and media. The thinking usually starts with some arbitrarily¹ fixed amount

¹ One method in common practice for arriving at advertising appropriations is to use a certain percentage of sales, sometimes just because another company, apparently

of money to be spent on advertising. Certain media are thought of which can be bought in units so that the amount of space bought is equal to the amount of money to be spent. Premature appraisals and cost comparisons are made among various media. Obviously, one can neither appraise media for doing a job nor determine the amount of money required until he knows what that job is.

Steps to be taken in the study of any advertising situation, therefore, are developed in the following order:

- I. What are the primary and secondary objectives of the advertising?
 - A. To introduce a product?
 - B. To establish priority in a new market?
 - C. To change attitudes toward a product?
 - D. To encourage new uses of a product or to extend familiar uses?
 - E. To protect the market from competition?
- II. What groups of people must be influenced, directly and indirectly, in order to accomplish these objectives (the number, location, income, age, sex, occupation, or other characteristics of each)?
 - A. Present or potential users of the product?
 - B. Those who influence the present or potential use?
 - C. The distributive organization?
 - D. Company personnel?
- III. What is the message to be communicated to each of the above groups?
 - A. What should the general nature of the appeal be—logical, emotional, or both?
 - B. What is to be the specific content of the message—product uses, “reason why” copy, educational, mere statement of a word or phrase?
- IV. What time limits are involved *i.e.*, how quickly must our objectives be accomplished and what risks are we willing to assume for the sake of speed?
- V. Which media can be employed to perform this advertising job most effectively and most economically among each group to be reached?
 - A. General types of media?
 1. Newspapers—city, small-town, county, Sunday, daily, weekly?
 2. Magazines—general, class, farm?
 3. Outdoor—posters, painted or electric signs?
 4. Direct mail—letters, catalogues, specialties?
 5. Radio—spot, sectional, or national broadcasts?
 6. Car cards?
 7. Trade publications?
 8. Business publications?
 9. Package inserts, booklets, circulars, folders, house organs?
 10. House-to-house methods—sampling, couponing?
 11. Dealer cooperative methods—displays, demonstrations, part-paid advertising?

similar, spends about the same percentage of sales for advertising. A noticeable confusion exists, here, between general principle and individual plan of operation. It is all right to apply an advertising principle to companies which are not alike in all respects, but it may not be all right to apply the same plan of operation to those companies. As we shall see, no two advertising problems are exactly alike in all respects. Even if there were two businesses whose advertising problems were identical, it might be dangerous for one manufacturer to be guided by what another had done, *i.e.*, to assume that the other had solved the advertising problem in the best possible way.

12. Publicity—theatres, schools, plant tours?

13. Movies?

B. Specific plans for the use of any type of media?

1. Time of use—hour, day, week, month, season?

2. Extent of use—size, volume, and frequency permitted by various amounts of money?

VI. What appropriation is necessary to accomplish the objective?

No advertiser can ever study long enough or discover facts enough to reduce his advertising decisions to a certainty. There is always an element of speculation in attempting to forecast results, and assumptions must always be involved. But not many advertisers have gone as far as they might to reduce the element of chance in their assumptions.

Before satisfactory answers can be secured to some of the above questions, it is usually necessary to conduct an inquiry¹ in relation to the product itself, the market for the product, and the entire distributive system, employed in moving the product to the consumer.

The Advertising Objectives. Sometimes the objectives of advertising can be defined in a general way in advance without very much study. A manufacturer may have the general problem of introducing a product for the first time, of introducing his product to new users, of stimulating the use of his product among old users, or of protecting his market from competitors. But before he can make the definition of his objectives very specific, he is usually forced to conduct some kind of an inquiry among those groups of people whom he is attempting to influence either directly or indirectly. And in the process of such study he gets a clearer conception and definition of the characteristics of the various groups whom he wants to influence. In addition, he can get some indication of the resistance or acceptance that his product experiences among these various groups. And such information may be used as a guide in constructing the message which is likely to be most effective.

Ordinarily, it is much easier to discover the characteristics of those groups of people to be influenced than it is to determine what information about the product will prove most effective in turning these groups of people toward it. In preparing a message for potential consumers, it is easy enough to build up certain logical reasons why consumers *should* want to use a product, but logical reasons are not necessarily the most effective ones to be offered in advertising a product, for the consumer is not always motivated by reason. For example, one manufacturer changed the packaging of his product so that it would reach the housewife in an air-tight condition. In interviewing housewives and getting their attitude toward this new package, it was found that housewives did not talk about the fact that the new package was air-tight, but consistently used the word "sanitary" in describing their conception of the advantages of the new package. The word sanitary, therefore, assumed an important place in the advertisement of this new package.

Time Limitations. All advertising programs have some time limitations. Ordinarily, however, these limitations have come to be so commonplace (because we think in terms of days, weeks, months, or years) that we take them for granted. But in some cases, special time limitations may be

¹ See Chap. I on Market Research and Analysis.

important. For example, the manufacturer of seasonal, novelty, fad, or temporary-style merchandise is obliged to exploit his market within a limited time. Or the manufacturer selling a product whose patent rights will soon expire may be very much interested in getting all the profitable business he can, and in establishing his position in the market, before his patent privileges expire.

The Selection of Media. After a manufacturer has secured reliable information concerning the groups he wants to reach, what he wants to say to them, and how he wants to say it, the next question is what media can be employed to perform this advertising job most effectively and most economically, within the time limits involved.

Wherever assumptions are made, the selection of media *from that point* may be very logical and the quarrel is not with the logic that is employed as much as it is with the assumptions that are made to start with. These assumptions may have been accurate at one time. But unless one continually keeps in touch with changing conditions in the market and among media, his assumptions may soon become obsolete. Or the manufacturer may have been working on a certain group of assumptions for years without having sufficient facts to support any one of them.

The effective selection of media necessarily involves the use of experimental campaigns. And this subject is discussed later under the general head of measuring advertising effects. A preliminary appraisal of media, however, can usually be made in advance of trial campaigns.

Newspapers and Magazines. Whenever newspapers or magazines have been tentatively selected there are certain points which might be considered in attempting to arrive at an indication of the relative value of various media within a given classification.

It is very difficult in a brief statement to convey anything like a complete understanding of all the factors which underlie such an appraisal. But an outline of some of the more vital points that should be considered is offered as follows:

I. Characteristics of circulation.

A. Quantity of circulation, including an examination of:

1. The trend in the amount of circulation, and a study of the reasons for this trend.
2. Secondary readership.

B. Distribution of circulation, by locations.

C. Selectivity of circulation, the characteristics of readers, which correspond with characteristics of groups to be influenced, including such data as age, sex, intelligence, occupation, income, or ownership of real or personal property.

II. Costs.

A. The gross cost of an adequate schedule.

B. The page or line cost per unit of circulation.

C. The estimated percentage of "groups to be influenced" among the readers and the consequent costs of effective circulation.

III. The contents of the medium.

A. General character of editorial treatment.

B. Evidences of reader response to content.

- C. Harmony between editorial treatment and the proposed advertisement.
- D. The advertising content.
- IV. Life of the medium.
- V. Use of the medium in combination with other media.
 - A. The efficiency with which its circulation supplements that of other media which may also be used.
 - B. Advantages or disadvantages of any forced combinations involved.
- VI. The mechanical arrangement of the medium.
 - A. The visibility of various positions.
 - B. Printing and appearance.
- VII. The trade or merchandising influence or service of the medium.
 - A. Special or plus services of the publication that assist in promoting the sale of the product.
 - 1. Among retailers and wholesalers.
 - 2. Among consumers.

Trends in the quantity of circulation are sometimes important. In those cases where an unusual growth has been experienced, some study might be made of the method for obtaining this growth in an attempt to learn whether the outstanding merit of the medium is responsible or whether forced circulation methods have been used and, in any case, to find out how such conditions affect the value of the medium for the specific product at hand.

Any definition of selective circulation must be thought of in terms of the product itself. For instance, a circulation which might be considered good for advertising a soap product may conceivably be considered poor for advertising a radio. Selective circulation for any manufacturer is that circulation which reaches the people through whom he can do the most business. It not only varies widely for different advertisers, but it is likely to vary over a period of time for any single advertiser.

Some attempts have been made to measure the selectivity of various circulations by offering information about readers in relation to their age, sex, intelligence, occupation, income, and ownership of real or personal property such as homes, automobiles, telephones, radios. And although these general measures might be used to serve as rough guides, the most reliable measures for any given manufacturer are those which have some direct relation to the need for and purchase of that individual manufacturer's product.

Sometimes it is possible to determine quite closely what proportion of total circulation may be considered effective and, in these cases, it is possible to base advertising costs upon that portion of the circulation rather than upon total circulation.

For example, a manufacturer made a sample study of the subscribers of two newspapers and found that only about 20 per cent of the readers of one medium belonged in groups that he was attempting to reach, whereas something like 65 per cent of the readers of a second medium were in these groups. The second medium promised to be the more profitable one for him to use, even though the rates per thousand of circulation in both media were about the same.

An examination of editorial content should lead to the consideration of means of adapting the advertising message so that it is in harmony with the

editorial matter. In some cases, the manufacturer may detect unusual opportunity for "tuning in" his message.

In trying to appraise media, one caution is recommended, *i.e.*, it may be more dangerous than helpful for anyone to attempt to make comparisons among various media within a classification and then attempt to build up a rating of these various media that will be universally applicable. For each product offers a different combination of emphases in relation to the various points included in the previous outline. Whenever one attempts to weigh these various factors he should do so in relation to a specific product.

Then too, changing conditions in markets and in media require a periodic appraisal of all media used and no check list or formula for rating media can be used as a substitute for study.

Manufacturers have frequently considered that a magazine or newspaper which carries a large amount of advertising on products similar to their own is therefore an appropriate medium for them to use. It is sometimes difficult for a manufacturer to resist the temptation of going into a leading medium—just because the leaders are there and he likes to be classed among them. His case may be very different from the leaders in the field and even though it is not, the use of advertising media, even by large advertisers, is not yet based on sound study in a sufficiently high percentage of cases to warrant the general assumption that a medium is good just because others are using it.

If a manufacturer's study of media leads him into the use of a medium that is most used by competitors, all well and good. But it might be dangerous for him to assume that, because a medium is most used, it is the best one for him.

Outdoor Advertising. Similarly, if outdoor advertising has been tentatively selected, there are certain preliminary comparisons of various outdoor media on the basis of such points as:

1. The number of people who view the display.
2. The percentage of these who belong in groups to be influenced.
3. The manner in which they pass the location—by foot, auto, street car, train—and whether they pass in a rush or at leisure.
4. The extent to which the display is likely to dominate the location.
5. The flexibility in the possible use of various outdoor media in relation to time, place, and space.

Radio. Or if radio has been selected for a trial, various broadcasting stations may be given a preliminary appraisal on the basis of such points as:

1. Power of the station (in watts) and the consequent distance it can communicate a message.
2. Position on the dial.
3. Clearness of the channel.
4. Station hours of operation.
5. Station hours available.
6. Popularity of station among groups to be influenced.
7. Competition for attention furnished by other stations at any time under consideration.

The main purpose of these preliminary appraisals is to guide the selection of media or methods within a given classification that promise to be best within that class. The more that facts are used to support the definition of

the advertising job to be done, the more intelligently can media or methods be appraised and selected. And the more these appraisals and selections are followed up by measures of the effects of their use, the earlier this body of fact can be employed to contribute to the support of assumptions which must be made every time a medium is selected. Without facts to help support an unbiased selection, one is much more likely to be susceptible to pressure exerted by publishers and other space sellers who, after all, are, in some degree at least, motivated by their own interests.

To sum up, there is no contention that the selection of efficient media or methods can be reduced to a certainty. But it is readily acceptable that the more facts we put into, and the more opinion we take out of, the basis upon which our assumptions rest, the higher our batting average of successful selections should be. This program involves the whole question of the measurement of advertising effects.

III. THE MEASUREMENT OF ADVERTISING EFFECTS

It would be difficult to select a subject more controversial than the measurement of advertising effects. Some flatly say "It can't be done." Others contend that it can be done and that it is possible to take the guesswork out of advertising. But while the two sides have been debating, a few have been quietly engaged in impartial study. And in the last ten years, some progress has been made by these few who have been experimenting with actual situations.

While it is true that some advertising methods lend themselves to measurement more fully than others, the author has not yet encountered any use of advertising that does not lend itself to measurement of *some* significant effects *provided* the job of measurement is approached by the experimental method.

Those who say "It can't be done" contend that the effects of advertising are so mixed up with the effects of all other kinds of sales efforts that it is impossible to isolate them. But throughout the development of all science, the favorite refuge of those who have not known how to do a thing has been, "It can't be done." In any field of learning it is only since men have evolved methods for measuring, summarizing, and recording their experiences that we have derived much benefit from these experiences. And one of the main reasons why we have benefited so little from the rich advertising experience that is behind us, is that few methods have been developed for measuring the results of this experience.

Not many years back, manufacturers were spending their energies opening up new and virgin markets. Under such conditions, the results of their advertising were usually so clear that there was little need to apply litmus paper tests and microscopic examinations. But in the present era these manufacturers face a different marketing situation in which satisfactory results of advertising are less likely to be assured in the absence of intelligent planning—planning that must be guided by the close measurement of advertising experience.

Any advertiser knows what he spends for advertising. And if these expenditures produce any tangible effects, those effects find their way into the profit and loss statement. But the effects of other work are in the profit and

loss statement too. And how are you going to unscramble them? Granted, it is difficult to do. But so is measuring the effects of various foods and stimulants upon the human system. What is more complex than untangling causes and effects in the human system? But medical science is gradually solving such complicated problems. We couldn't measure electricity until instruments were devised for doing so. And even now we don't know what electricity is. But we can measure the effects. Scientists have devised instruments and set up laboratory experiments on all kinds of problems solely because most conditions are scrambled, and in order to measure the effects of any one of them it is absolutely necessary to set up some experiments in which an attempt is made to hold all other factors constant and comparable, while the effects of any given factor are being measured. Few have deliberately attempted to set up experimental studies and thereby separate the advertising elements which so many dismiss as immeasurable. But some such experiments have been set up. And whenever they have been set up by one who has made intelligent use of governing principles, significant measurements have been obtained.

Although cases that permit the removal of all guesswork are very rare in advertising, yet the cases in which sufficient evidence of productiveness can be secured to serve as a dependable basis for judgments are numerous enough.

There is some literature¹ on the measurement of advertising effect. For the most part, however, it falls short. It deals with inquiries, attitudes, opinions, and then stops. Not until measures of advertising results are scientifically tied up with the costs of advertising and with actual sales and profits, do they graduate from the stage of academic interest into that of practical value.

That part of the literature which deals with "inside" laboratory tests is particularly difficult to apply. After all, a manufacturer's laboratory for testing his advertising is his market. That is where advertising effects are produced. That is where method should be developed.

Practical methods that have actually been developed in the field for measuring advertising effects will now be presented under three general headings:

1. The measurement of the effects of house-to-house advertising.
2. The measurement of the effects of special dealer advertising.
3. The measurement of the effects of mass media advertising.

Measuring the Effects of House-to-house Advertising. *Selling vs. Sampling.* The manufacturer of a food product employed two house-to-house methods for advertising his product. The advertising manager thought that "House-to-house selling is the most effective way of advertising the product among non-users simply because the purpose of the advertising is to encourage consumers to try the product and you can't get people to give a product a fair trial unless they pay something for it." The sales manager, however,

¹For bibliographies on the subject see MABEL GRAGG, "Testing Advertising," pp. 111-123, *Harvard Business Review*, October, 1930; DONALD R. G. COWAN, "The Measurement of Advertising Effect," pp. 12-13, *Bulletin of the Advertising Federation of America*, 1930; WILLIAM J. REILLY, "Marketing Investigations," pp. 122-127, The Ronald Press Company, 1929.

felt that "If you *give* a person a full-sized package of a product they'll be sufficiently grateful to you to give it a fair trial."

Four cities were selected—two comparable¹ cities in each of two territories. In each territory, city A was used for house-to-house sampling and comparable city B for house-to-house selling. In each territory, a composite of all remaining cities was used for purposes of control. In each case the house-to-house crews were asked to save the addresses of those homes into which they had succeeded in getting a package of the product. Two months after the work was completed in each city, those who received a trial package of the product were interviewed in order to learn (1) whether they had been using the product before or whether they were non-users before they got the trial package; (2) whether they liked or disliked the product; and (3) whether those who were non-users when the work was done had used the trial package and had bought² a package of the product in the regular way at the grocery store.

One year later the non-users who had bought were interviewed in order to learn whether or not they still used the product and about how much they used per month.

In following up these two methods in the field, *gratitude* was found to be the key word in expressing the attitude of housewives who had been given a trial package of the product from the advertising crew. The actual testimony of housewives indicated that many non-users gave the product a fair trial because they had accepted a full-size trial package and, in the process of trial, they had become converted. House-to-house sampling reached non-users *intensively*.

On the other hand, house-to-house selling reached only those comparatively few non-users who were willing to buy the product at the time from the advertising crew.

The main results³ of these experimental measurements are offered in Table I.

¹ In selecting comparable locations for the experimental study of any product, it is necessary to exercise particular care in choosing locations that are alike from the standpoint of any known factors that affect the sale of that product. In any given case, there are a large number of such factors, including those in relation to consumers, to competition, to previous advertising, to methods of distribution, to efficiency of the distributive organization, and to general business conditions. In the study of markets, it is impossible to choose two locations exactly alike, but one can select locations which are sufficiently alike (from the standpoint of the known factors that affect the sale of that product) to be considered comparable. Then if any differences in advertising results are secured, one can be reasonably sure that these differences are due to variations in advertising methods rather than to differences in the trial market. In the study of this particular product, we had found, through earlier studies, that the main factors affecting the resistance of the market, were: the percentage of the total population who do not use the product, the nature and price of competing products, and the type of home.

² Difficult information to get. The technique for getting it is discussed in Chapter I, p. 22, *The Difference between Answers and Facts*.

³ The behavior of sales in control locations was sufficiently level that no correction factor had to be introduced. If sales in control locations had increased or decreased appreciably during this experimental work, it would have been necessary to subtract the increase or add the decrease in arriving at the results attributable to house-to-house advertising.

But the study could not stop with a measurement of results. Costs had to be taken into account. Before judgment could be passed on either method, costs of securing a new customer by each had to be calculated.

In this case (see Table II) it cost the manufacturer 40 cents to deliver a trial package of his product to the housewife by the house-to-house sampling method in city A, territory 1. Seventy-five per cent of all families to whom a trial package was given, were non-users. By dividing 75 per cent into 40 cents we get 53 cents as the cost per non-user who received a trial package. Only 22 per cent of all those families receiving the trial package were "non-users who later bought a package of the product in the regular way at the grocer's." Dividing 22 per cent into 40 cents gives the "cost per non-user who bought at the grocer's"—\$1.82.

TABLE I.—STATEMENT OF RESULTS

Location and method	Per cent of the total housewives receiving the trial package who were:		
	Non-users	Non-users and later bought at the grocer's	Non-users, who bought at the grocer's, and who still used the product one year later
Territory 1			
House-to-house sampling in city A.	75.0	22.0	13.0
House-to-house selling in city B.	20.0	5.2	3.1
Territory 2			
House-to-house sampling in city A.	84.0	26.0	16.0
House-to-house selling in city B.	18.0	5.0	2.9

One year later, when these non-users who bought were interviewed to find out how many of them still used the product, it was found that 13 per cent of the total families receiving the trial package could now be classified as "non-users who later bought at the grocer's and who still used the product one year later." In other words, 13 per cent of the total could be considered as new users secured, and dividing 13 per cent into 40 cents gives us a cost of \$3.08 per new user secured, by house-to-house sampling method in city A, territory 1.

Similarly the cost per new user secured¹ was calculated for the other three cities included in our study, shown in Table II.

¹ The use of such cost comparison is not without its assumptions and limitations. In the first place, these cost figures are based only on measured results. Many immeasurables may escape our attention. For instance, a newly acquired customer may not

TABLE II.—STATEMENT OF RESULTS AND COSTS

Location and method	Cost per housewife who received a trial package	Per cent of total housewives receiving the trial package who were non-users	Cost per non-user who received a trial package	Per cent of total housewives receiving the trial package who were non-users and later bought at the grocer's	Cost per non-user who bought at grocer's	Per cent of total housewives receiving the trial package who were non-users, who bought at the grocer's, and who still used the product one year later	Cost per non-user who bought at grocer's and who still used the product one year later
Territory 1							
House-to-house sampling in city A.....	\$0.40	75.0	\$0.53	22.0	\$ 1.82	13.0	\$ 3.08
House-to-house selling in city B.....	0.58	20.0	2.90	5.2	11.15	3.1	18.70
Territory 2							
House-to-house sampling in city A.....	0.38	84.0	0.45	26.0	1.46	16.0	2.37
House-to-house selling in city B.....	0.62	18.0	3.44	5.0	12.40	2.9	21.40

The information given in Table II is sufficient to show that the house-to-house sampling method was a much more economical one than house-to-house selling. But, before house-to-house sampling could be passed upon as profitable, some approximation of what a new user was worth had to be developed.

Calculating on the basis of (1) a net profit¹ of 5 cents per package, (2) an average consumption of two packages² a month for a new user, the promised profit per new user was about \$1.20 a year.

In this case three years was considered as a reasonable time to wait before the profit secured from a new user's business would pay for the cost of securing this new user. Net profit, on new business then, would be realized three years after the advertising work was done. The estimated worth³ of a new user, therefore, was set at \$3.60.

With this estimated worth of \$3.60 per new user, the sampling method for securing new users at a cost of \$3.08 in city A, territory 1, and at a cost of \$2.37 in city A, territory 2 (see Table II), promised to be profitable. But the fact that this house-to-house sampling method promised to be profitable in one or two territories did not prove that it would be in other territories.

The Effect of Various Factors on the Cost of Sampling. Even though the cost per family reached in two cities is approximately the same, it is dangerous to assume that the cost per new user secured will necessarily be the same in those two cities. For example, in cities where the percentage of regular users of the product was high, the cost of reaching non-users tended to become rather high. Similarly, in weak territories where the percentage of regular users was low, the cost of reaching non-users by the sampling method tended to become relatively low. All of which suggested the obvious conclusion that in strong territories, the per cent of regular users reached can become so high and the consequent costs of reaching non-users can so increase as to make the work unprofitable. This immediately provoked the question of how strong a territory must be before sampling costs become excessive.

In an attempt to answer this question let us refer to Fig. 6. This exhibit shows the point at which the cost of securing a new user by house-to-house sampling began to exceed the estimated worth per new user. Along the base of the exhibit we have a scale which shows the per cent of total housewives who are regular users of the product at various stages in the

only use the product but also may influence others to use it or tend to prevent old users from discontinuing the use of the product. On the other hand, some who tried the product and disliked it might influence others against the product. The assumption in this case is that advertising methods which compare favorably on the basis of measured results might be expected to compare favorably on the basis of results not measured. Because all costs are necessarily allocated to those results which are measured, these measures can be more safely used as a basis for judging the comparative values of various methods than for judging their absolute values.

¹ Not including the cost of house-to-house advertising.

² Established in field survey.

³ This assumes that the new users who still used the product at the end of a year will continue to use it at least two years more. The validity of this estimated worth, however, cannot be established until two more years have elapsed and these same new users who continued to use the product at the end of a year are interviewed to learn what per cent of them still use the product at that time.

development of a market. In this exhibit we have two vertical scales, one, along the left, to show the per cent of total housewives who belong in various groups of non-users, and another, at the right, to show the cost per new user

FIG. 6.—Showing the point in the development of a market at which the cost of securing a new user by house-to-house sampling begins to exceed the estimated worth per new user.

secured. Opposite the point on the base line which indicates a market with 25 per cent regular users or 75 per cent non-users, we find the points plotted in connection with house-to-house sampling in city A. territory 1. Opposite

the point on the base line which indicates a city with 16 per cent regular users, or 84 per cent non-users, we find points plotted in connection with house-to-house sampling in city A, territory 2. Similarly, other actual cases were used to plot points upon which the various curves are based.

The most significant observation to be made from this exhibit is that the cost per new user secured begins to exceed the estimated worth of a new user at a point opposite 38 per cent on the base scale. This means that whenever the percentage of housewives in a city who use the product regularly, exceeds 38 per cent, the cost of securing a new user by the house-to-house sampling method begins to exceed the estimated worth of a new user.

But there are other differences in markets which affect the return that a manufacturer can get from an advertising expenditure. For example, in this particular study certain sections of the market were found, in which the prices of competing products were so low and the price resistance to the

TABLE III.—STATEMENT OF RESULTS AND COSTS

		Non-users	Non-users and later bought at the grocer's	
City 1*.....	\$0.12	100†	32	\$0.37
City 2†.....	0.12	100	17	0.71

* City 1 water analysis: 28 to 33 grains (water generally considered to be hard).

† City 2 water analysis: 8 to 10 grains (water generally considered to be of medium hardness).

‡ An entirely new product.

product so high, that an adequate return on the house-to-house sampling method was practically impossible.

To illustrate further the effects which market differences might have upon the market resistance to a product, let us take an entirely different kind of product—a soap powder. A soap manufacturer found that, of all the house-to-house advertising methods that he had been using, house-to-house sampling was the most effective for introducing a soap powder that had water-softening properties. But because the product had these properties he wanted to find out what effect hardness of water might have on the market reception to the product and the consequent costs of securing new users. In order to indicate the results secured and the consequent costs involved in securing new users in two cities that had different hardness of water, a study was made which resulted in the information presented in Table III.

Using the method presented in Fig. 6, the worth of a new user was estimated and the cost of securing a new user was found for cities of different

hardness of water. How hard a city's water supply had to be in order to promise an adequate return on the use of house-to-house sampling was thereby determined.

Other House-to-house Methods. Extensive use was made of the above methods in measuring the results of other house-to-house advertising such as house-to-house couponing, combination sampling-couponing, group products sampling and couponing.

Measuring Special Dealer Advertising. Demonstrations vs. Specials. The manufacturer of a grocery product employed two special dealer advertising methods. The first plan was to employ demonstrators who sold the product in retail stores. The second plan was to advertise in the newspapers special sales of the product through which retail grocers offered a premium with each purchase of the product.

Those who received a package of the product by either of these methods were interviewed two months after they had received the package to find out what percentage of those reached were non-users who later bought at the grocers. One year later the non-users who bought were interviewed to learn if they still used the product. In other words, the same kind of follow-up was made on these methods as has already been described in detail in the study of the house-to-house methods.

The main results of these measurements are offered in Table IV. As the figures show, premium sales by grocers showed itself to be the more economical plan for special dealer advertising, and in reaching a decision on the types of locations where these special sales among dealers could be conducted at a profit, the same method was followed as is presented in Fig. 6.

TABLE IV.—STATEMENT OF RESULTS AND COSTS

Method and location	Cost per housewife who received package	Per cent of total housewives receiving package who were non-users	Cost per non-user who received package	Per cent of total housewives receiving package who were non-users and later bought at the grocer's	Cost per non-user who bought at the grocer's
Store demonstration sales					
City 1.....	\$0.28	30	\$0.93	9	\$3.11
City 2.....	0.30	34	0.88	12	2.50
Premium sales by grocers					
City 1.....	0.08	25	0.32	5	1.60
City 2.....	0.09	28	0.32	6	1.50

Measurement of Window Displays. Under the head of special dealer advertising, some attempts have been made to measure¹ the value of window displays. One procedure in setting up such a study is given as follows:

¹ FREYD, MAX, "The Experimental Evaluation of a Merchandising Unit," *Harvard Business Review*, vol. IV, pp. 196-202.

1. A standardized window display was prepared and installed in a number of drug store windows for the purpose of answering the following questions:

- a. What is the immediate effect of the window display on sales in the store in which it is used?
- b. What is the duration of this effect?
- c. In what size and class of stores does the window display have the greatest effect on sales?

2. In company with the manufacturer's salesman, the investigator called on a large number of drug stores and arranged for an accurate check of sales of the product before, during, and after the window display was used.

3. The display was kept in the window for a period of two weeks. Sales were checked at each store in the following way. The investigator called at the store once a week, commencing four weeks before the installation of the display, and ending four weeks after it was taken out of the window, a total of ten weeks. At each call, an inventory of the product was made and the proprietor was asked the amount he had bought during the preceding seven days. From these successive inventories, the amount sold each week could easily be calculated and sales curves drawn for each store demonstrating the effect of the display.

Without going into detail concerning the control of minor variables, the answers to the three questions studied in this case are:

- a. Most window displays brought an immediate increase in sales.
- b. When the display was removed sales in that store descended to their previous level.
- c. Most favorable returns were secured among stores which had cut-prices on the product, and which demanded some reimbursement for the use of their windows.

Measuring the Effects of Mass Media. And now we come to the most difficult job of all—measuring the effects of the use of mass media. Here, one is faced with essentially the same kind of job as in measuring the results of the use of methods just given. The main difference is this. When a manufacturer uses a mass medium his audience is, of course, dispersed and difficult to locate¹ (except in a mail campaign).

Early Attempts to Measure Effects of Mass Media. Some of the early attempts to measure the effects of mass media advertising consist of interviewing prospective consumers after the advertising has been run (usually on a new product) in an attempt to learn what percentage of these prospects know of the product and what percentage have bought or used the product. These early attempts usually include no plan for separating the effects of advertising from the effects of other marketing efforts by measuring conditions in comparable territories, some of which were subjected to the influence of mass media advertising and some of which were not. But in some instances those who have conducted such studies have, more by accident than by plan, found themselves in possession of data that afforded some comparisons between conditions in territories which had been heavily covered by advertising and territories which had been lightly covered.

¹ Sometimes it is possible to get the names and addresses of subscribers to newspapers or magazines in a few sample locations. Wherever this is possible, field studies are much less tedious and expensive.

For example, a paint manufacturer had a product which was largely used in industry. He employed national magazines and farm papers to introduce this product for household use and he wanted to check up on the results of his advertising. Personal interviews were secured among housewives to learn:

1. What per cent had ever heard of the name of the product?
2. What per cent were able to associate the name of the product with the product itself and with the use of the product in the home?
3. What per cent had ever bought or used the product?

This survey showed a fairly consistent knowledge and use of the product among housewives in larger cities and in very small towns. In the middle-sized cities, however, there was considerably less knowledge and use of the product.

A subsequent analysis of the circulation of media used, showed that the magazines used were primarily reaching larger cities; that the farm papers were, of course, reaching the very small towns.

In the absence of any great differences in the use of other marketing efforts in various-sized cities and towns, this manufacturer automatically possessed, somewhat by accident, evidence which permitted him to compare relative effects of his mass advertising in locations where circulation coverage had been concentrated and in locations where circulation had been weak.

And as a by-product, he was reminded that such an analysis of circulation should have preceded, rather than followed, his selection and use of mass media.

Now let us take an example of an experimental study of mass media effects which illustrates a more careful and planned procedure.

A national advertiser having national distribution and using magazines and newspapers in the cost ratio of two to one, desired to determine the effect on sales of his newspaper advertising.

Sales for the last ten years had been divided into three territories, namely, Pacific section, central section, and Atlantic section. All newspaper advertising had been segregated according to these three divisions. The advertising appropriation had been allocated according to native white population. Per capita native white sales seemed to be about the same for each of the three sections. Therefore, in summary, we have the United States divided into three sales units, each unit having been treated with the same proportionate advertising influences.

In 1929, it was decided to discontinue all newspaper advertising in the central states area for a period of three months, namely, April, May, and June; then, for the subsequent three months, July, August, and September, to cut all newspaper advertising in the Atlantic section. Thus for one three-month period the lack of newspaper advertising would be felt in the central section and for the next three-month period the lack of newspaper advertising would be felt in the Atlantic section. All other marketing efforts were purposely kept normal for each of the three units.

Each unit was regarded as a separate entity and a trend of sales was fitted to each. By eliminating seasonal influences, monthly variations were determined for each division.

Using the Pacific Coast section as the control section, bench marks were obtained for determining what sales should have been in the central section. When these bench marks were compared with actual sales, the results for the three-month campaign were that less profit was lost, as a result of decreased sales, than the saving effected by the cut in advertising. The same procedure was used in measuring the results from the lack of advertising in the Atlantic section.

To determine what the influence of additional newspaper advertising would be, the regular advertising appropriation was doubled during the months of January and February, 1930, in the states of Oklahoma and Missouri. All other states received the regular appropriation.

By using sales in the non-test states as control states, bench marks were determined as to what sales would have been in Oklahoma and Missouri. The profits resulting from increased sales were less than the additional cost of the advertising.

Advertising Costs vs. Advertising Results. Any comprehensive study of advertising effects (regardless of advertising method used) should ultimately lead to the discovery of that point at which advertising costs begin to exceed the estimated worth of the results secured. Such studies may involve measures of the results on sales and profits including any one or more of such points as are offered in the following outline:

CONDITIONS WHICH MIGHT BE CHECKED "BEFORE," "DURING," AND
"AFTER" PERIOD OF EXPERIMENTAL ADVERTISING

I. In relation to the consumer.

A. Percentage of consumers who know of the product.

B. Consumer use of the product.

1. Percentage of regular and occasional users.
2. Percentage of consumers who use the product for various purposes.
3. Reasons given for using the product.
4. Reasons given for not using the product.
5. Characteristics of users and of non-users.
6. Trends in the use of the product.
7. The extent to which users also use competing products.

C. Consumer buying habits.

1. Quantities bought.
2. Frequency of buying.
3. Entrenchment of brand habits.

II. In relation to the distributive system.

A. Retailers.

1. Number.
2. Size.
3. Kind.
4. Geographical location.

B. Retail sales.

1. Turnover, by types and locations of stores.
2. Volume, by types and locations of stores.

C. Retailers' sales efforts.

1. Physical arrangement of stock.
2. Willingness to suggest or recommend the product as opposed to substituting some other.

3. Attitude toward company's advertising and sales program.
- D. Amount of personal selling required to retailers.
 1. Number of salesman's calls per day.
 2. Frequency of calls on individual dealers.

(If jobbers are used, similar conditions should be checked among jobbers.)

III. In relation to costs.

A. Effects on various costs of marketing.

1. Market study.
2. Advertising.
3. Selling.
4. Transportation.
5. Overhead.
6. Expense.

B. Effects on various costs of production.

1. Raw materials.
2. Plan and design.
3. Labor.
4. Machinery.
5. Overhead.
6. Expense.

When a manufacturer can trace sales into certain self-contained markets that are coextensive with the territories reached by the advertising, he is in position to measure total effects from his office records. When he cannot he is forced into sample field studies. But even the manufacturer who can trace his sales into self-contained markets must extend his studies into the field, if he is interested in analyzing total effects among different classes of people or inquiring into the conditions responsible for these effects.

Limitations of Inquiries as a Measure. Counting inquiries has been a popular method for attempting to measure mass media results—probably because this method uses data readily available. Inquiries can be used as a relative measure in some cases, notably by those who sell exclusively by mail and who key their individual advertisements in such a way that inquiries and sales growing out of these inquiries can be associated with individual keyed advertisements. These general methods have been ably presented by Falk.¹

But even in such cases, inquiries do not give the answer to advertising effectiveness until the sales growing out of these inquiries are traced. Only when sales flow entirely through inquiries—either by mail or personal follow-up—can one be sure that he is tapping all important sources of business by following the trail of inquiries.

Unfortunately, inquiries have commonly been held up as a measure of advertising effectiveness to many organizations which do not fit this description—with little or no attention given to the assumptions and limitations involved.

Inquiries themselves may be quite meaningless in relation to sales and profits. Is there anyone who has not heard the story of the Scotch maid

¹ FALK, A. T., "Analysing Advertising Results," *Harvard Business Review*, January and April, 1929.

who mailed letters to herself so that the postman (whom she liked but who never looked at her) would be sure to call every day? It is not so difficult to prepare an advertisement that will pull inquiries. But they may mean little more than the letters the Scotch maid sent to herself. The advertisement that pulls most inquiries may not be worth most at the profit line. Theoretically, it is possible to get a comparative measure of the value of two advertisements designed to accomplish the same purpose through the relative number of inquiries received from those two advertisements. But in those cases where the bulk of the manufacturer's business comes from those who are not heard from, inquiries are impractical for three main reasons:

1. It is difficult, if not impossible, to secure circumstances which are sufficiently comparable.

2. It is dangerous to assume that the measured results are safely indicative of the total results.

3. There are many other more direct and more inclusive measures of advertising effect that can be used with so much less risk.

The Need for Continuing Experiments. Even though a manufacturer has been advertising for years it might be dangerous for him to be too well satisfied with his present advertising practice. He may be employing the wrong type of media. He may be using the right types of media but using the wrong media within a given type of classification. Or he may be right in types of media, and right on specific media within each type and yet be wrong in the use that he is making of these media, *i.e.*, he may be using the wrong size of space, frequency of insertion, or nature of appeal.

It is not necessary to try to answer all of these questions within a few months, or a year, or even five years. But if one is ever to be in a safe position to answer any one of them, he must make a beginning. He must begin with some systematic attempt to record the history of his advertising experience. How much more all of us would know about advertising today, if advertisers had begun ten years ago, and had continued, to study even part of the effects of their advertising.

Instead of attempting to determine in advance exactly how he will spend his entire advertising appropriation for the coming year, any advertiser, who had not already done so, might profitably begin by inaugurating an experimental year in advertising. At the beginning of his year, he might set aside for experimental work part of his appropriation, using the other part just as he ordinarily would.

Before many weeks have elapsed some of the results of the experimental work may be available and the manufacturer can use this information as a guide in effecting any desired readjustments in the advertising program.

If for example, he experiments with three methods, and the first proves to be wholly unsatisfactory, the second produces sufficient results to indicate that it is profitable, and the third shows results that promise to be extremely profitable, he might decide to discontinue the first method entirely, to continue the second method on a modified scale, and to place primary emphasis on the third method which appears to be most profitable.

But in any event, at the end of that year he should have a fuller knowledge of the most profitable methods for doing his advertising job.

But testing and experimenting will not be finished at the end of that year. Business is dynamic. Situations change. The job of keeping in step with change is a continuing one. The use of a medium that is profitable this year may soon reach the point of diminishing returns.

Only when those in advertising possess the patience and the ability to analyze and to measure, does advertising begin to assume a scientific complexion.

But some will say, "You're making this thing entirely too complicated. Why try to measure the immeasurable?"

Popular reasons given for *not* experimenting are: "It's too much extra work," or "Our company is too small for such a detailed analysis."

But the *real* reason sometimes runs deeper. All of us are more likely to defend than we are to question what we have done. None of us enjoys admitting his mistakes. Experimenting usually uncovers errors of omission and commission, and not until we acquire a genuine hospitality toward information that shows us where we have made our mistakes, can we possibly make the most of our advertising experience.

CHAPTER III

MERCHANDISING : ADAPTING THE PRODUCT TO THE MARKET

By H. A. RICHMOND, *Director Publicity and Advertising Service, Policyholders Service Bureau, Metropolitan Life Insurance Company*

The problem of product adaptation to market requirements or conditions has become increasingly serious in the last decade. Many factors have contributed. Primarily, the marked tendency toward price competition has been the urge behind the growing attention given to merchandising.

In meeting the competitive situation, the first reaction of business management appears to have been to increase the intensity of selling operations—to spend more for advertising, to inaugurate sales promotion plans, to cultivate closer relations with dealers.

While such devices have helped, it has become increasingly evident that they have not provided a complete solution of the marketing problem. Increased advertising and sales promotion have been balanced by similar activities on the part of competitors, and profitless selling has been the outcome.

The merchandising function has grown out of the search for devices which would help in removing products from the realm of price competition. Certain manufacturers have found themselves relatively immune to price selling. In most of these cases the product has been of a "specialty" nature. It has had distinct characteristics setting it off from other similar products, and making it preferred.

It was to be expected that manufacturers generally—observing the enviable position of those selling specialty goods—should seek for themselves the same advantages. They have sought to achieve for their products a position of stable demand and stable price. They have been asking themselves the question, "What can I do to make my product a specialty?" It is at this point that the merchandising problem begins.

What Is Merchandising? A wide variety of meanings are attached to the term merchandising. This is no doubt due to the fact that the function to which the term is now being generally applied has been clearly recognized and defined only in recent years. The loose usage of the term doubtless reflects to some degree the fact that the function is in an evolutionary stage.

In its early usage, merchandising was a term for describing the activities of the merchant of those days—buying and selling goods for profit. As such, it would hardly apply to selling activities of the manufacturer, either then or today.

Many writers on marketing subjects have used the term merchandising almost synonymously with marketing. Frequently, it is applied to activities such as sales promotion, dealer cooperation, pricing, and the like. But the term has come to have a more specialized and exact meaning. It has been longest in use in the retail field and is there used most specifically. Retail merchandising is now generally defined as the *selection* of merchandise which will meet the needs, wants, and desires of consumers.

Manufacturers are more and more thinking of merchandising in terms similar to the retail usage. The main distinction is that for "select" the manufacturer must substitute "create." For him merchandising is the creation of goods which people will want to buy. One authority has defined merchandising as "that phase of marketing which centers around the product itself." The term applies to those activities directed toward stimulating consumer demand for a product by changes in the product itself or its adjuncts. Merchandising precedes production. Advertising and sales promotion, likewise, aim to stimulate consumer demand, but they start where merchandising leaves off. Merchandising consists of putting sales interest into product as part and parcel of it. Sales promotion consists of creating sales interest through activities extraneous to the product and coming after the processes of production are completed.

It is through merchandising that production and selling come closest together. Merchandising implies that a definite effort has been made, in advance of producing goods, to determine their sales possibilities. It signifies the coordination of manufacture and sale, taking into account consumer requirements and demands and the manufacturing facilities of the plant.

Objectives in Merchandising. Fundamentally, the purpose of merchandising is to bring product and market into such a relationship that capacity output of the plant can be marketed on a profitable basis. It aims to attach special consumer appeal and interest to the product by incorporating into it distinctive features that the public wants.

Merchandising aims to extend or improve the usefulness of a product, or make it more attractive, and thereby widen its demand. Increased demand permits price stabilization at levels which permit a profit. It tends to subordinate the price element in the sale and thereby helps remove the product from competition.

It is the purpose of merchandising to make staple products into specialties and keep specialties from becoming staples. Staple goods tend to be sold on an exclusively price basis. There is little to distinguish the product of one manufacturer from that of another. But when distinctive features are added the product tends to be set apart in the minds of consumers from other like products.

The specialty item, however, frequently does not remain so. Competing manufacturers are likely to incorporate similar special features into their own products. In this way, what was originally an improvement becomes a staple characteristic. The first fountain pen, for example, was decidedly a specialty, but when this pen came into general use the specialty element no longer adhered to it. With the introduction of the self-filling feature a specialty item was again created by the manufacturer responsible. Still later color was introduced with like effect.

The continual introduction of specialty features presents a serious problem from the standpoint of production. Manufacturing efficiency is at the peak under mass production. Large-scale economies may be made possible by standardization of product. The sales organization, however, is inclined to want constant change. If a competitor introduces some feature which gives distinctiveness or individuality to his product, the salesman generally wants to be able to offer customers a similar product. The production executive is likely to regard such continual changes as unnecessary and tending only to increase manufacturing costs. It is the function of merchandising to determine just how far standardization may be sacrificed to consumer demands for change and variety, and at just what point loss of sales offsets possible production economies.

Putting Sales Interest into the Product. A wide variety of tools are at the disposal of the manufacturer for making his product more interesting to consumers, and for putting the entire output of his plant on a profit-producing basis. These include:

1. Improving the product's performance by adding refinements and conveniences.
2. Developing new uses or extending present use by changes which will make the product:
 - a. Demanded by more classes of users.
 - b. Used more hours in the day or days in the year.
 - c. Used in a wider geographical area.
3. Changing style or design.
4. Introducing color.
5. Making the size, quantity, or unit of sale more convenient.
6. Improving the package.
7. Putting sales value into the name.
8. Adding new items or lines.
9. Associating the product with other products in selling.
10. Reducing or simplifying line.
11. Standardizing quality.
12. Price lining.
13. Utilizing waste or by-products.
14. Supplying full directions for use.
15. Adding service features.

Every detail of the product itself and any of its adjuncts which may affect consumer satisfaction are proper subjects for investigation from a merchandising standpoint. Most of the items listed above relate to characteristics or attributes of the product itself and their importance as factors in increasing sales appeal is readily apparent. In some, like the questions of adding new items to a line or simplifying a line, the question of sales appeal may be less important than that of distribution cost.

The service factor has a sales promotion as well as a merchandising angle. In general, services not directly related to the product, or services rendered in advance of the sale, may be considered as sales promotion. Service definitely associated with the product—such, for example, as keeping a mechanism in good working order—may be considered as an adjunct of the product itself and hence primarily a merchandising problem.

Product Improvement. Changes designed to increase the utility of a product or the satisfaction derived from its use have frequently provided a powerful stimulus to consumer demand. The automobile industry affords an excellent example of merchandising through the continuous introduction of improvements which have tended to make owners of older models dissatisfied. The public has come to expect certain improvements with each new model introduced.

Product improvement is by no means limited to mechanical devices. It may be applied to drug products, food products, clothing, and in fact, to nearly every line of merchandise. Typical examples include yeast in candy form, castor oil that is tasteless, skinless frankfurters, screens that roll up, hosiery with extra thickness knitted at toe and heel, creosote-treated shingles. The list might be extended to great length.

In general, increased utility appears to be a less effective merchandising factor in products which are primarily style goods than in others.

As a guide for the development of improved features many companies have made consumer surveys to find out possible objections to their products or difficulties in use which might be eliminated.

Developing New Uses. Certain manufacturers have been notably successful in increasing consumer demand for their products by extending the range of use. In some cases the new uses developed have become a more important factor in sales than the original use for which the product was intended.

An outstanding example of the development of a new use which has tremendously enlarged consumer interest in the product is afforded in the yeast-for-health campaign of the Fleischman Yeast Company. Drano, a product originally intended to clean out obstructions in drain pipes, is being merchandised as a cleaner for garbage receptacles, refrigerators, pots and pans in which grease or food has been burned, and similar uses. Listerine, originally an antiseptic, became in turn a deodorant and a hair tonic. Unguentine developed from a surgical dressing for burns into a general all-purpose ointment for burns, cuts, boils, and the like.

In many cases, new uses for a product can be developed without making changes in the product itself. This was the case in most of the examples cited. Sometimes, however, incidental equipment must be provided. An interesting example of this is to be found in the case of Sterno, a non-liquid fuel sold in cans. The president of the company manufacturing this product states¹ that the product was originally considered to be primarily for outdoor use in summer. A survey revealed many other year-round uses: by travelers, on trains and in hotels; by theatrical folk for preparing make-up; by doctors and nurses for sterilizing; in the home, for heating baby's milk, curling irons, water for shaving, and for other purposes. It was found that many of these uses would be greatly facilitated by providing special equipment. Accordingly, such devices as toasters, vaporizers, shaving sets, flatiron holders, baby milk warmers were developed. As a result, the seasonal slump in sales during the winter is stated to have been eliminated.

The development of new uses has proved effective in freeing a product from dependence on a single trade or class of consumers, eliminating seasonal

¹ *Printers' Ink Monthly*, May, 1929.

fluctuations, and in general stabilizing sales. New uses, however, are rarely pulled out of thin air by some genius among a company's personnel. Manufacturers who have been most successful in the use of this merchandising tool have usually gone to the consumer for their inspiration. Consumer surveys and prize contests appear to be regarded as two of the best methods for getting facts about new uses.

Changing Style or Design. In the case of goods where the style or fashion element predominates merchandising activity generally centers around this factor. For such items as jewelry, silverware, and many articles of apparel, and house furnishings, style changes are probably the primary basis for stimulating consumer interest. More attention has doubtless been given to this phase of merchandising than any other. When used successfully styling has often proved an open sesame to profitable selling. On the other hand, poor styling has been a prolific cause of business reverses.

Style movements are stated by Dr. Paul Nystrom in his book, "Economics of Fashion,"¹ to be the result of rather powerful forces in human nature. Styles which are currently in vogue are defined as fashions. Fashion, according to Dr. Nystrom, is a force much like public opinion. It is impossible to determine when or where a fashion will start, or what causes it to assume the particular form that it takes. Though the essential nature of fashion may remain unexplained, it may be put to work as a tool in merchandising, just as electricity is harnessed even though its exact nature is unknown.

A number of guiding principles have evolved from the experience of manufacturers who have been notably successful in hitching their merchandising program to the style factor. These may be summed up as follows:

1. Fashions cannot be created in the sense of being prescribed by so-called fashion arbiters, such as Paris couturiers, for example.
2. Fashions move from the top—from the leaders in society—down to the masses.
3. Fashions move from the style centers and the larger cities to the smaller towns and outlying sections. Formerly this movement was relatively slow. In more recent years, however, due to the speedy dissemination of style news, through the movies, radio, and printed word, new styles spread over the entire country within the period of a few weeks or months.
4. Fashions vary to a certain degree in different geographical areas. Certain styles may have a limited vogue in the South, for example, or on the Pacific Coast. An illustration of this is afforded by the fact that brown eggs are at a premium in Boston while white eggs are preferred in New York.
5. Fashion changes are rarely abrupt. They develop with gradually increasing intensity and taper off in the same way. They proceed with a wavelike motion.
6. The length of life of a particular fashion varies with the nature of the merchandise. According to Dr. Nystrom, dress accessories, touches of color, inexpensive novelties may be in vogue for only a season. Such items as length of skirts or silhouette in garments move in cycles covering several years, while fashions in furniture and home architecture, for example, may have a life extending into decades.

¹ The Ronald Press Company, 1928.

7. Good merchandising demands working *with* style movements rather than *against* them. Corset manufacturers some years ago, for example, tried through advertising and sales promotion to offset the declining vogue for their product. Though a comprehensive program was carried out the desired result was not obtained.

8. The direction, intensity, and geographical boundaries of style movements can be gauged with considerable accuracy. Many companies make it a practice to measure such movements in the form of statistics which may be reduced to an index number basis, plotted in graph form, or recorded on maps.

9. Style movements tend to spread over all lines of merchandise, exerting a parallel influence on lines quite unrelated. The modernistic movement, for example, has influenced architecture, silverware, furniture, floor coverings, watches, and numerous other products. There are, in fact, few lines which have escaped its influence. The manufacturer of a particular product, therefore, usually finds it desirable to key it to the general style trend evidenced in other lines.

10. Best results are achieved in style merchandising when the product is neither behind nor ahead of current fashion. One extreme appears to be about as objectionable as the other.

Introducing Color. Color is one of the most flexible tools at the disposal of the merchandiser. It has incited fresh consumer interest in many products which because of their nature make the application of other merchandise appeals difficult. Bathroom fixtures, wall tile, face brick, sheets, towels, and kitchenware are products which illustrate the point.

The introduction of color has induced retailers to give many products space in window and counter displays which would not otherwise have been given. Using color in popular-priced alarm clocks, for example, brought this product off the shelves of many a retailer and put it onto the counters and into the store windows. Some of the outstanding facts from the experience of manufacturers who have introduced color into their products include the following:

1. The use of color adds to the display value of the product or package.
2. Color helps to make the product remembered by the consumer.
3. Colors must be selected with reference to the colors of other products with which the particular item is to be associated in use, so as to insure color harmony. The lamp shade manufacturer, for example, studies the colors in vogue in draperies, floor coverings, and the like.
4. Vivid, intense colors must be used with caution and sparingly.
5. Products with large areas appear to better advantage in subdued colors.
6. Certain colors appear to be better adapted to certain products than others. Thus, it is stated that pink kitchen utensils are much less in demand than are other colors.

Making Size or Quantity More Convenient. It is important that the size of the product or the unit offered for sale be examined from time to time to find out whether changes are needed to bring it into line with consumer demand and increase its appeal. The trend today is toward smaller sizes and units. It is in evidence in houses and automobiles, as well as drug and grocery items.

Too large a package may be a definite hindrance to sales. Consumers may hesitate to buy because the package or product may take up too much space in the medicine cabinet or on the kitchen cabinet shelf, or because they fear that it may spoil before being used up. It is reported by Ray Giles in "Breaking Through Competition"¹ that the manufacturer of an item sold in a 25-cent unit found that he sold twice as many pounds of his product when the package was reduced to one-third of the original size and offered at 10 cents.

In certain cases, an increase in the size of the package or unit of sale has stimulated demand. The National Lamp Works is stated to have obtained beneficial results through introducing a home assortment carton in the shape of a toy house, containing six lamps. An executive of a leading department store reports that introducing the sale of hair nets in packages of a dozen increased sales by four times.

A survey of users of the product appears to be the quickest and easiest way of finding out whether the sales unit should be made larger or smaller.

Improving the Package. Package design has proved to be the merchandising tool *par excellence* in the drug and grocery fields. It has extended, however, to nearly all lines where it can be applied. In fact, it has entered fields that would have been considered impossible a few years ago. Fresh meats are now being packaged. So are lumber, coal, dry goods, and numerous other articles—usually with satisfactory results in respect to consumer interest.

It is stated by Walter S. Hayward in "Sales Administration"² that the consumer "wants a container which will satisfy his desire for attractive appearance, keeping qualities, utility, convenience and ease in handling, correct quantity and correct price, and many other factors."

Some manufacturers have hesitated to change a package design which has been long in use, even though they recognize it as unsatisfactory. They fear that the change will cause loss of sales. The experience of a number of companies in making sudden and rather radical changes in their package designs has shown beneficial rather than harmful results.

Among recognized fundamentals in good packaging may be mentioned the following:

1. The package or container should have the maximum of utility. The bottle for Blue Label Ketchup, for example, was improved by making the neck very wide.

2. It should be in harmony with the product. Packages such as are suitable for beauty preparations, for instance, would hardly be suitable for many other products.

3. It should be in keeping with current style trends in packages and thus appear modern and up to date. Simplicity and color are modern keynotes.

4. It should bear a family resemblance to other packages in the company's line.

5. It should be so attractive in appearance that it will not only attract attention on the retailer's shelves but will also induce him to display it on counters or in windows.

¹ D. Appleton & Company, 1926.

² Harper & Brothers, 1927.

6. It should be so designed that the name will stand out distinctly no matter which way the package is turned.

Putting Sales Value into the Name. The name of a product is quite as much a part of it as the package in which it is purchased. It may be a sales asset or a liability. While it is generally considered more difficult to change a name than a package, there are instances where it has been done with excellent results. For example, Franken and Larrabee, in "Packages That Sell"¹ report that the Westinghouse Electric and Manufacturing Company changed the name of their new iron, after a test, from "Spencer thermostatic" to "click iron." The Royal Worcester Corset Company dropped the name "corset" and called their products "lingerie plastique."

Changes of name have been successfully accomplished through prize contests in which names were submitted by the contestants. The publicity attendant on the contest has served to carry consumer acceptance for the old name over to the new. In other cases, the new trade name has been added to the old. Subsequently on the package and in the advertising logotype the size of the old name has been gradually reduced and finally omitted entirely.

Some of the accepted principles governing name selection include the following:

1. The name may be suggestive of the product, as for example, Rolcreens, Sealcones, Life Savers.
2. It may suggest qualities of merit in the product, such as Real Silk, Holeproof, Nofade.
3. It may suggest the source or origin of the product, such as Cream of Wheat, Philco.
4. It should be short, easy to pronounce, and easy to spell. Lux, Keds, Duz, Drano, Loma are typical examples.
5. Separate names should be used for different grades.
6. Legal requirements must be met.

Adding New Items or Lines. Since consumer demand is always dynamic rather than static, it follows that new needs are constantly arising. The alert manufacturer is on the watch for these developments with a view to introducing new products to meet them, provided such products can be fitted into the company's production and distribution operations. The company introducing the new item enjoys the advantage of goodwill attaching to other items in the line, and hence may have a lead on competition.

Sometimes the need for development of new items or lines hinges on the necessity for making use of surplus productive equipment. An illustration of this is afforded in the experience of the Bigelow-Hartford Company. It is stated² that the change in consumer demand from narrow-width sewed carpets and rugs to the seamless variety forced the company to install broader looms. The problem then arose as to what could be done to save the investment in the old equipment. The search for new lines which might be produced on the old looms led to the manufacturing of footmats for use in motor

¹ FRANKEN, R. B., and C. B. LARRABEE, Harper & Brothers, 1928.

² "Use of Research in Developing Old Products and Introducing New Ones," Policy-holders Service Bureau, Metropolitan Life Insurance Company, 1928.

cars, decorative mats for general home use, picture mats for nurseries and the like. In this way, merchandising avoided the loss of a substantial investment.

Frequently the development of new items or side lines is conditioned by a desire to reduce distribution costs through spreading overhead over a broader line. In many cases, the salesman who has more lines to offer is more likely to make a sale. On the other hand, diffusion of sales effort over too many lines may be harmful.

In introducing new or side lines it is generally considered best to select one which can be handled by the existing sales organization. It is also helpful if the new lines supplement the old ones from a seasonal standpoint, so as to smooth out the sales curve so far as possible.

Associating the Product with Others in Selling. It has often been found that demand for a product may be increased by associating it with other products. Usually the product with which the tie-up is made is a related one. Thus, Wilson Brothers have associated a shirt and a necktie in a package with excellent results.

The importance of the ensemble idea in buying gives particular point to product association as a merchandising tool. It has been very successfully used by the Pioneer Suspender Company to stimulate interest and get retail display for their products. Their suspenders are styled to harmonize with ties and their garters are designed in line with current vogues in men's hose.

Frequently a feature has been made of some special combination of products. Such a specialty package was the combination of a new-model Gillette safety razor, a tube of shaving cream, and a shaving brush recently featured for a short time.

Product association is especially effective in such forms as gift packages, or in connection with seasonal occasions such as Valentine's Day, Mother's Day, Hallow'een, Easter, and the like. An interesting illustration is afforded in the combination of a pound of Apollo Chocolates and a novel in a single package. The plan includes an arrangement like that of the Book-of-the-Month Club, by which subscriptions are taken for one package a month for a period of six months or a year. A new novel is, of course, included each month. An example of timeliness or seasonableness in a package is the Mother's Day package of the Pepperell Manufacturing Company. This consists of a box containing an assortment of sheets and pillow cases in a selection of colors to blend with any bedroom color.

Reducing or Simplifying Lines. This merchandising factor is governed mainly by considerations of cost—both of production and distribution. It presents a most serious problem in connection with styles, patterns, sizes, and colors, tending not only to increase production costs but also to pile up inventory costs all along the line of distribution.

Many manufacturers follow a definite program of discontinuing certain numbers or items as new ones are introduced. The linoleum manufacturer, for example, discontinues the poorest selling patterns as new ones are introduced. The temptation is frequent to continue a number or pattern because some slight demand for it still exists. In many cases, however, yielding to the temptation has meant the sacrifice of profits.

Merchandise analyses with a view to eliminating unprofitable items have often shown that a large percentage of a company's sales volume is made on a small percentage of the items sold. As a result of such an analysis the Regal Shoe Company reduced the number of its styles from 2,500 to around 100. Sales statistics by items provide the basis for such analysis.

Standardizing Quality. Standardized quality or uniformity of performance of a product is generally recognized as a merchandising fundamental. Without such uniformity consumer satisfaction is not likely to be maintained. Lack of standardization in grades of lumber, for example, undoubtedly has been a contributing factor to the development of consumer interest in substitutes. Lumber manufacturers have come to realize the merchandising weakness of their position and are now offering their product in both grade-marked and trade-marked form.

Likewise, the manufacturers of spun silk, or tub silk, as it was formerly called, found the public apathetic to their product in no small measure because of the lack of any uniform standard of quality. In the program of rehabilitation undertaken by the Spun Silk Research Committee, one of the first steps has been to set up standards of quality which must be rigidly adhered to by producers engaged in the cooperative sales promotion effort.

Uniformity of performance has proved an effective merchandising tool for flour manufacturers, baking powder manufacturers, and many others. Uniformity of taste is considered vital in all food products where taste is concerned. The problem of maintaining standards and achieving uniformity is, of course, one for the production department to solve through testing laboratories or otherwise.

Price Lining. The matter of pricing can be a merchandising help or a hindrance. In arriving at a price figure manufacturers have sometimes added together the cost of production, the cost of selling, and a margin for profit. Such a procedure, from a merchandising standpoint, is generally considered unsound. Rather, the procedure followed should be the reverse. This means that the manufacturer starts with a particular price objective in view and then builds his product to meet it.

Price lining as a merchandising aid has long been recognized by retailers, particularly in the department store field. Some stores feature only the higher priced lines and cater to a more or less exclusive trade. Others cater to the lower class trade, and still others aim to satisfy the demands of high, low and medium income classes. The automobile field presents a parallel situation. There is a growing tendency on the part of each manufacturer to offer cars in price ranges which meet the pocketbooks of the various income groups. General Motors offers cars which run the whole gamut of price. Studebaker offers cars in four price groups ranging down from Pierce-Arrow at the top.

The merchandising value of producing different price lines lies in the fact that this opens a wider market to the manufacturer. There is little competition between \$1,500 cars, for example, and \$1,000 cars, between \$15 shoes and \$10 shoes, or between \$10 shoes and \$5 shoes. There is a relatively distinct market for each price group. The manufacturer selling in only one group is, therefore, selling in a limited market. By introducing additional price lines he is enabled to reach a wider range of income classes.

Successful price merchandising involves a decision by the manufacturer as to just what class of consumers he shall seek to interest in his product. If he is a shirt manufacturer, for example, he may decide to offer a product at \$1.39 or at \$5.00. But it is important that the decision be based on a recognition of the fact that two distinct markets are involved and on knowledge of the number of consumers in each class and their buying habits.

Leading merchandisers consider it important that different grades of an article be sold under separate brand names. Some go so far as to handle sales on an entirely separate basis. The Melville Shoe Corporation, for example, offers three price lines of shoes, with John Ward at the top, Rival Shoes in the middle and Thom McAn at the bottom. A separate chain of stores is operated for each of the three lines.

Utilizing Waste or By-products. Efficient and profitable operation of a manufacturing enterprise demands that waste or by-products be turned into sources of profit so far as practicable rather than remaining a charge against profits. Numerous examples are to be found where this end has been accomplished. Thus a lumber manufacturer developed a substantial toy business by utilizing waste ends. A knitted underwear manufacturer found that waste cuttings could be made into toys, and in time the toy end of the business became more important than the garment-manufacturing end. To utilize the sulphur in copper ore a copper refining company started the manufacture of sulphuric acid. Later to use the great quantity of acid produced the manufacture of chemical fertilizer was undertaken. A chemical manufacturer developed a synthetic gypsum building block which utilized the calcium sulphate produced as a by-product.

In many cases technical research has opened the door to new profits through by-products or waste utilization. In other cases the solution has been found mainly through market studies. When the new product is an outgrowth of technological research it must, of course, be analyzed from the standpoint of consumer acceptance or demand before being put on the market.

Supplying Full Directions for Use. While this factor in merchandising may usually be taken for granted, there are cases where special considerations have turned it into an important factor in stimulating consumer interest. Recipes for food preparations and general directions covering application and use are of course the rule. It is obvious that the explanation should be adequate and given in clear, simple terms.

One point often overlooked is that instruction in the use of the product itself may be secondary to instruction in operations to which the use of the product is incidental. The White Sewing Machine Company, for example, recognizes that knowledge of how to use their product is decidedly secondary to knowledge of the art of sewing. Purchasers are therefore given a course in sewing.

A similar example is afforded by the experience of the Russian Cement Company, makers of Le Page's Glue. The company recognized that the use of glue for *mending* things about the house would always be a restricted one. If they could sell their product for *making* things their market would be greatly enlarged. Accordingly, an experienced woman with the proper

qualifications was employed to devise all sorts of articles which could be made in the home with the aid of Le Page's Glue. Wooden devices which could be made by boys, as well as novelties for favors, gifts and the like, were developed in great number. The company prepared a number of instruction books telling just how the different items could be made. Instead of giving these away they were sold at 10 cents each. Many hundreds of thousands have been distributed.

The Stanley Works, to increase the use of its tools worked out plans for making various household articles and toys by amateurs. Later a book entitled "How to Work with Tools and Wood" was issued. This was sold at a nominal price. The plan proved effective in increasing sales of Stanley tools.

Service as a Merchandising Appeal. For many items of merchandise of a mechanical nature, such as oil burners, automobiles, mechanical refrigerators, and the like, service in the sense of being able readily to secure the services of a mechanic for adjustments or repairs is highly important to continued satisfactory use. Service without charge for a limited period is usually a part of the sale.

A different type of service is that rendered by printing organizations in helping customers to prepare copy and similar services by magazines and newspapers for their advertisers.

The tendency today is to add service features as a means of stimulating consumer interest in and satisfaction with the product, and make it preferred to what competitors offer.

Are Merchandising Problems Limited to Particular Lines of Business? There is a tendency in some quarters to regard problems of merchandising as the particular concern of manufacturers of style or fashion goods. This point of view, however, is today being generally discarded. The manufacturer of staple merchandise or industrial goods may be somewhat more limited in merchandising methods which can be applied to his line but he still has a wide freedom of choice.

It is perhaps true that merchandising presents a more serious problem to the manufacturer of wearing apparel, jewelry, furniture, and the like, than to the sugar refiner or to the manufacturer of a machine tool. But the refiner of sugar—a staple product—can apply the methods of merchandising in the matter of packaging, in the name, in the introduction of special features such as making lumps shaped like the diamonds, hearts, clubs, and spades on playing cards, or making lumps flavored with lemon. Likewise, the machine tool manufacturer today is applying merchandising principles in the design of his product, in the introduction of color, and in a variety of other ways.

In general, the trend of the times is toward change and improvement in all lines of merchandise. The manufacturer who has continued making his product just as for years previously has found himself not infrequently displaced by some competitor who has applied effectively the tools of merchandising. Marketing authorities agree that the manufacture and sale of every product—whether luxury or necessity, specialty or staple—gives an opportunity to apply merchandising principles and methods. It is on the

Refinements and Conveniences. The consumer appears ever ready to accept the product which embodies some improvement or refinement. When the self-starter was introduced in automobiles, public demand soon forced all manufacturers to include it. Balloon tires soon displaced the older type of tires. Shock absorbers are now demanded as standard equipment.

The demand for labor-saving devices permeates every field—the home, the office, the factory. There is a preference for products which are ready to use. Bread is being sold already sliced. More and more, the housewife is buying delicatessen goods—ready to serve.

The manufacturer who can introduce a change in his product which will meet this demand for convenience and luxury is likely to find himself well repaid.

Attractive Appearance. The demand today is for products which are good looking. At one time utility and performance were features of prime concern in buying. Now these are taken largely for granted. Beauty, style, color—these are the factors which are tending more and more to influence sales. The live merchandiser, therefore, is constantly alert to changes which will improve the appearance of his product—or the package, in case it reaches the consumer in this form.

Harmony with Surroundings. Today is the day of the ensemble idea. Not only must the product be good looking but it must harmonize with its surroundings, or the setting in which it is to be used. In the living room, for example, draperies, rugs, furniture, and other items must conform to a particular style or to particular color combinations. In wearing apparel, in home building, there is the same insistence on harmony of style and color. Manufacturers, therefore, find it wise to study the products with which their own products are to be associated in use and to make adaptations where indicated.

Smaller Units of Purchase. In this day of smaller homes and apartment-house living, consumers want their purchases to be in small units. Lack of space for storage makes objectionable the purchase of large size units from the drug or grocery store. The consumer prefers to buy his food "hand-to-mouth" and so the grocery manufacturer finds that it pays to provide smaller-sized cans and jars and bottles. We see the introduction of 5- and 10-cent groceries. We find a growing demand for midget radios.

Research to Find Out What the Consumer Wants. Knowing what the consumer wants in respect to the merchandise he buys need not be a matter of guesswork or playing hunches. It is true that certain people appear to show special ability in gauging in advance consumer acceptance of a particular product. They seem to possess a sort of intuitive sixth sense as to what will "take" with the public.

Sound merchandising practice is tending more and more to steer away from reliance on the prophesies of such geniuses who make forecasts of consumer acceptance on the basis of their intuitive "feeling." The reason is that such judgments have all too often proved wrong. The cost of developing a new product or modifying an old one is often substantial. The possibility of loss in case of an unfavorable response on the part of prospective buyers is too great to take unnecessary risks.

It is being increasingly demonstrated that the trial and error method of finding out how a new product will be received can be avoided. By the use of research manufacturers today are putting new products on the market with a high degree of certainty of success.

An interesting example of how accurate forecasts of consumer acceptance can be made by scientific methods is afforded in the experience of the Du Pont Viscoid Company. Their procedure, as described by C. F. Brown, director of sales, at a meeting of the American Management Association,¹ is as follows:

The company recognized the need for restyling its line of toiletware known as Pyralin. A staff of stylists was engaged to find out what the public wanted. Style sources in the United States and Europe were contacted. A new line in new designs and colors was developed and given the name "Lucite."

To find out whether consumers would like and buy the new line it was decided to make a survey. An investigator was given sample sets of the new Lucite and sample sets of the old Pyralin with a view to submitting them to various types of consumers and getting an indication as to preference. In the course of the sixty days scheduled for the survey the "votes" of 1,048 women had been obtained. These were made up of business and professional women, club women, college students, and art students and instructors.

The tabulation of the results showed a 69 per cent preference for Lucite and a 31 per cent preference for Pyralin. On the strength of this preliminary survey the new product was launched on the market. The company's sales and profits subsequent to this broke all previous records. In the year following, Lucite sales proved to be 65 per cent of the total as against the forecast of 69 per cent, and Pyralin sales were 35 per cent as compared with the forecast of 31 per cent.

In making the survey, consumers were asked to indicate their preferences for nine individual designs and color combinations. There was a surprisingly close correlation between the preference given in the test and actual sales afterwards.

Methods of Determining Consumer Demand. A variety of methods are used by manufacturers to insure that their product will find favor with consumers. For the most part these may be grouped under the following headings:

1. Keeping in touch with sources of information on trends in consumer demand, such as trade publications, fashion magazines, and the like.
2. Getting the advice of style specialists.
3. Checking trends in the same or related lines—for example, making fashion counts.
4. Getting the opinions of dealers, store buyers, and the like.
5. Getting advance opinions from possible consumers.
6. Getting reactions of consumers after actual trial.
7. Collecting and analyzing sales statistics.

These various methods of finding out what the consumer wants are not mutually exclusive. A single manufacturer may use all of them. Many

¹ Marketing Executives Series, No. 64.

manufacturers use several of them regularly. In general, the more methods of checking used the greater the certainty of the forecast.

Keeping in Touch with Sources of Style Information. Reference has already been made to the fact that style as a merchandising factor affects nearly all lines of products—if not in the product itself then in the package or container. Furthermore, a particular style trend may influence a wide variety of unrelated products. For example, color has not only entered into the home—from cellar to roof—but it has likewise entered into locomotives, adding machines, telephone receivers, and a thousand and one other items. Stream-lining—first introduced in aircraft—has extended to automobiles. Many similar cases might be cited.

For these reasons, leading merchandisers make it a point to keep closely in touch with current style trends through trade and fashion magazines, style bureaus, and the like. In bringing out new styles or designs they aim to relate them to the trends which they find to exist in other lines. The Elgin National Watch Company, for example, in seeking to introduce modern art into its products, is reported to have consulted leading couturiers in Paris.

In the wearing apparel field, where fashion is a factor of primary importance, many manufacturers keep close contact with places and events which draw society leaders, for it is generally recognized that style percolates from the top downward. Paris, Deauville, Miami, Newport, and other haunts of society are covered by style reporters, as are races, polo matches, and other sporting events attended by society.

Employment of Style Specialists. The increasingly important place of style in merchandising has emphasized the place of the specialist in this field. The stylist, or style advisor, is a person who has made a specialty of studying style trends and the influences governing them. It has been said that style is an expression of a mode of living, that style changes have their roots deep in human nature. It is agreed by style specialists that, broadly speaking, styles are not created at will, but rather that they emerge out of the habits and customs of the age.

Proper styling, then, is a broad complex problem which goes beyond the scope of activities of the shop designer of the old school. Manufacturers who are notably successful as merchandisers usually employ stylists who devote their time exclusively to the manufacturer's problems or who are engaged on a consulting basis. The stylist points out the nature and direction of the style trend to be followed. The company designer interprets this in the particular merchandise to be produced.

Where the styling work of a company is highly important and extensive, the work of the stylist may be extended to the point where a style bureau is organized. The Stehli Silk Company, for example, maintain a style bureau which collects and analyzes available style data with a view to determining trends and to anticipate fashion demands by at least three months. The bureau maintains a branch in Paris. The New York Office is stated by Paul Bonner, vice president of the company, in an address before the First Southern Manufacturers Sales Conference, to be "in constant touch with the fashion editors of the fashion publications, with the stylists and fashion advisors of the large department stores and department store groups, and with the

leading American dressmakers and designers. Furthermore, they cover as style reporters the large social events of the season." According to Mr. Bonner, the style expert armed with information such as the style bureau supplies has little necessity for guesswork.

The members of the National Association of Retail Clothiers and Furnishers, according to Kenneth Dameron in an address before a meeting of the American Management Association, receive a compilation of opinions by twenty leading stylists as to style trends and best sellers in various sections of the country. Similar pooling of style information occurs in a number of other cases.

Checking Trends in the Same or Related Lines. One of the most common methods of checking trends in consumer demand for a particular line of merchandise is to watch what competitors are doing. If some new feature is introduced by several competitors and if leading stores push the new product, general consumer acceptance is indicated. Watching the advertisements in newspapers and magazines as a means of keeping in touch with new developments is common practice.

A more exact method of checking frequently employed is the fashion count. This involves placing investigators at strategic points, such as street corners, where there is a large number of passers-by, hotel lobbies, railroad stations, and the like. The investigator counts the number of people wearing or not wearing the particular items being checked. One of the rubber footwear manufacturers, for example, used this method to find out the relative popularity of different styles of rubbers, such as sandals, storm rubbers, and the like, and also of galoshes.

Getting the Opinions of Dealers. Many manufacturers make it a practice to secure opinions from dealers as to the probable reception by the public of proposed new products or new styles and designs. Sometimes the canvass of dealer opinion is made by the company's salesmen who may carry samples of the product or photographs.

Some companies employ special investigators for this work. Such surveys generally cover all the factors or agencies involved in distributing the particular product such as wholesalers, jobbers and others. In connection with the development of a new product for use in home building, for example, surveys have been made which covered not only building supply dealers but also architects and contractors.

One manufacturer follows the practice of sending questionnaires to dealers to secure style information. As the returns come in they are recorded on maps so that geographic differences as reflected in style trends will be indicated where they exist.

A few manufacturers have organized advisory councils of dealers for the purpose of maintaining closer contact—for giving the manufacturer the benefit of the dealer's point of view and for giving the dealer a voice in the determination of company policies. Such councils have proved helpful as a check in introducing new styles and designs.

Getting Advance Opinions from Possible Consumers. This device is particularly adapted to many types of merchandise and is rapidly gaining in popularity. It is used especially in the case of food products. Those contributing

information taste the new recipe and give their reaction, usually by indicating their order of preference for various samples submitted.

The same method is frequently used to forecast the popularity of new colors, new designs, new names, new packages. When properly used such tests forecast consumer acceptance with a high degree of accuracy. It is, of course, important that those contributing information in such surveys constitute a representative sampling of consumers who are expected to buy the product, and that the number tested be large enough to make the results statistically reliable.

The methods by which such consumer reactions can be obtained are various. In certain cases, questionnaires sent through the mail may be used. One manufacturer, for example, is reported to have asked the company's salesmen to secure from retailers a list of users of the company's products. These numbered thirty-eight, and the company was considering reducing the line. A total of about 500 names was obtained. To these was sent a letter asking the recipient to indicate on an attached check list the five products, in order of preference, which he would like to have retained should the company decide to reduce the line to five items. Those answering the questionnaire were offered a sample box of the company's latest product.

More common than the use of mail questionnaires is the practice of personally interviewing prospective consumers. This is frequently done by house-to-house visits. Some manufacturers station investigators in their dealers' stores to question customers. In other cases such tests have been conducted in classrooms, offices, at club meetings, food and fashion shows, and under a variety of other circumstances.

Getting Reactions from Consumers after Actual Trial. This appears to be a highly reliable method of predetermining consumer response to a new or changed product and apparently is growing in favor. In some cases, manufacturers make tests of this kind by giving the product to a number of consumers to try out. This method is particularly applicable to products which must be used over a period of time before consumer reaction takes definite form. The Fuller Brush Company tests each new item in this way.

A novel method of determining consumer response to a new electric iron is reported by Franken and Larrabee in their book, "Packages that Sell." With the first few hundred irons put on the market in Buffalo was enclosed a card which the consumer was asked to fill out and return to the company. The card called for information as to the buyer's attitude toward the new iron. As an inducement for sending in the card a side rest for the iron was offered.

The practice of testing consumer response in a limited area and extending marketing operations only if the test indicates a favorable reaction has been used by many manufacturers. Sliced bread, for example, is reported to have been tested out in particular communities. "Tiolene," a packaged motor oil, was marketed on a wide scale after tests in two cities showed consumer acceptance. Such examples might be extended at length.

Whenever it is practicable to test out consumer acceptance of a product in a limited way, before going into large-scale production operations, this

method is generally regarded as unsurpassed. For many products, however, the method is scarcely feasible. It is obvious that a new automobile model, for example, could not be tested for consumer acceptance in this way. The same applies in greater or lesser degree to most fashion lines.

Collecting and Analyzing Sales Statistics. The value of sales figures as a means of forecasting style trends and changes in consumer demand has come to be recognized only within comparatively recent years. When fashion trends were less clearly understood there was a tendency to regard them as developing more or less by chance and shifting their courses suddenly and without cause. This view has since been proved incorrect. It has been demonstrated that style movements proceed rather slowly. The fashions of next month and next year are in the making today.

The vogue for short skirts, for example, was in process of development for several years during which the length of skirts was gradually reduced. The present vogue for longer skirts is stated by style experts to have been clearly indicated two years ago, when this mode was being gradually adopted for evening wear.

By the setting up of proper sales records, therefore, it has proved practicable to forecast the direction and intensity of style trends with a fairly high degree of accuracy. The use of sales records as a basis for merchandise control has been more extensively used by retailers than by manufacturers. Successful retail merchandisers keep a close watch of sales figures for different classes of patterns, colors, textures, and the like, and in this way keep merchandise stocks in line with demand. The same method may likewise be used by the manufacturer.

Sales records for the first few months that a new product or design is on the market furnish an excellent index to the future. For example, it is reported by John Alcott, style advisor to Bird & Son, in an address before the First Southern Manufacturers Sales Conference that the rate at which a new rug design sells during the first three or six months furnishes a reliable basis for projecting the sales curve into the future.

The American Woolen Company is reported¹ to study the sales records of each fabric in the preparation of the new season's merchandise. Those most in demand are automatically repeated, sometimes with slight modifications. Numbers dropped are replaced by new designs. The same report states that the M. J. Whittall Associates keep an individual record of each pattern and coloring, covering the quantity of each on order and in stock as well as sold.

A number of companies make it a practice not only to compile sales statistics for their own use in deciding what items to continue and what ones to drop, but to pass this information on to their dealers as a guide in their buying. The Boyd-Welsh Shoe Company of St. Louis issues weekly to dealers a style report showing on a percentage basis the breakdown of sales according to materials, styles and the like. W. & J. Sloane of New York also publish to their trade stock sheets listing patterns in the order of preference as shown by total sales.

¹"The Use of Style and Design in Industry," Metropolitan Life Insurance Company.

Sales of merchandise to dealers do not always accurately reflect sales to consumers. There is always a certain amount of lag. Furthermore, dealers may be buying patterns or styles which accumulate in stock and later must be gotten rid of through special mark-downs. To overcome these difficulties and get sales statistics that reflect consumer demand in the most accurate possible manner, one hosiery manufacturer has adopted a plan for getting sales figures daily from certain stores in different parts of the country. Each night these stores send in a report on sales made that day on each number in the line. In this way the company can at once detect any falling off in the popularity of particular numbers and can gauge production operations accordingly.

Use of Style Indexes. The process of measuring the direction and intensity of style movements by means of sales figures has so completely demonstrated its value that it is being reduced to index form. Such index numbers may be set up to record fluctuations in demand, as measured by sales, for designs, colors, and in fact any other merchandising factor.

Cheney Brothers have been among the leaders in the development of such indexes. The Cheney Color Index showing the trends in demand for various color families was inaugurated some years ago. It is published monthly for distribution to the trade. Graphs are plotted showing the movement of each color family over a six-month period. The index is so made up that the average of all the colors plotted would be 100. As certain colors gain in popularity over the group average the index number for these rises above 100, and conversely, as the popularity of a color wanes in respect to the combined average its index number falls below 100.

Pooling of Statistics Showing Style Trends. It is obvious that the reliability of sales statistics or index numbers reflecting fashion movements is increased with any increase in the volume of sales represented. While the figures for a single company might not be highly reliable, figures representing the combined sales of several companies are much more likely to be so. By pooling figures in this way each cooperating company gains the benefit of more accurate information than it could possibly obtain by acting independently.

In recognition of these facts, companies in a number of cases have gotten together, usually through the medium of an established trade organization, to pool sales figures reflecting style trends. An example of such an arrangement is afforded by the Wool Institute. The mills in the institute membership report sales on a percentage basis broken down according to colors and patterns. The institute prepares a combined report which is sent to the members. In this way each member can know with considerable certainty just what designs and colors are enjoying popularity and what ones are on the wane.

Organization of Merchandising Activities. As merchandising has evolved as a separate and distinct function in marketing, and as the scope of merchandising activities has grown, it is natural that parallel changes in business organization should take place.

In the absence of definite organization in the company and of placing responsibility for merchandising, two counter tendencies are often in evidence. The sales organization is sometimes disposed to want changes made in the

product to match each innovation or feature offered by competitors. In this way the sales organization is in a position to satisfy objections of customers or meet any preference for competing products, aside from price considerations.

The production department, on the other hand, sometimes is inclined to question the value of frequent changes in the product. It is conscious of the production economies in a standardized product and is likely to associate increases in manufacturing costs with decreases in profits.

Merchandising, as already indicated, serves to coordinate the production and sales departments. Its function is to balance a possible increase in production cost with a possible increase in profits due to increased sales appeal in the new or changed product. Or, on the other hand, it must consider whether a saving in cost of manufacture may not more than offset the possible loss of sales through the discontinuance of the less popular items in a line.

Today, a growing number of manufacturers are recognizing the value of organizing for merchandising—of centering in one individual the responsibility for finding out what consumers want and interpreting it in terms of the company's products. Such an individual is usually given the title of merchandise manager, a title which has come into common usage in the department-store field. The functions of the merchandise manager in the retail field and in the manufacturing enterprise may be considered as practically identical in so far as they relate to keeping in touch with consumer demand. The major point of distinction lies in the fact that one *selects* from a wide variety of merchandise offered that which will conform to consumer demand, while the other *creates* merchandise that will meet these requirements.

From what has already been stated as to the growing tendency to reduce merchandising to a scientific basis—measuring consumer acceptance or demand by the application of research methods—it follows that the merchandise manager must be analytically minded. On the other hand, he requires imagination in order to develop new features in the product that will meet the characteristics of consumer demand which his studies have revealed.

Where the company employs a stylist this person is usually on the staff of the merchandise manager. Also the merchandise manager serves as the contact with the style consultant.

In companies which do not have an executive in the capacity of merchandise manager, a major part of the functions involved may be placed in the hands of the stylist, or divided between the stylist and some company executive. Where merchandising activities are not sufficiently extensive to require a merchandise manager, or the full time of a stylist, the employment of a style adviser may meet the situation.

The work of the merchandise division of the Gorham Company is typical of that in many other organizations. This division is charged with originating new styles and designs. The merchandise manager sends to the designing department requisitions for new designs, stating details as to style, size, capacity, weight, cost, finish, and other requirements. For a specific item, the finished drawing after being approved by the merchandise manager is

sent to the general superintendent to have a sample made up. If the item is not specific, a number of designs are prepared which are submitted to a merchandise committee made up of representatives of the design, merchandise, sales, manufacturing, and production departments.

Whether or not a merchandise department has been set up the practice of having new styles and designs considered and approved by a merchandise committee is increasingly being followed. Such a plan is used by the General Electric Company. For many years a committee of three members, representing the production, designing and architectural points of view, has passed on new designs, with a view to insuring practicability of production, maximum utility, and best possible appearance.

Whether a particular company should set up a merchandise department to give constant attention to the matter of product improvement or continuous adaption to consumer demand, appears to depend largely on the number of lines involved and the frequency with which changes are demanded. In cases where it is not considered necessary to organize a merchandise department it is often considered desirable to assign to one executive the duty of studying the company's merchandise with a view to improving it. In the opinion of merchandising authorities, there are few products which are not susceptible to improvement, either in utility, appearance, or otherwise.

CHAPTER IV

PRICE MAKING AND PRICE POLICY¹

By EDMOND E. LINCOLN, *Economist, International Telephone & Telegraph Corporation*

Influences Determining the Price Policy. What determines a company's price policy? Obviously, many of the determining factors vary from industry to industry and from one concern to another in the same industry. However, there are a few underlying principles which must be considered in all cases. The selling price of a commodity must first cover the cost of manufacture, including material, labor, and overhead, as well as administrative and selling expenses. There should then be a sufficient margin after all of these expenses are deducted, and after allowances have been made for ample depreciation, taxes, interest, and the like, to yield the seller a profit which is ordinarily considered "reasonable" for a business subject to the particular degree of risk. Without quibbling regarding the economic theories involved, this profit may be regarded as covering not merely a "fair return" on the owners' capital, but also an additional amount as compensation for the *risks* which have been assumed by the owners in the capacity of entrepreneurs. Accordingly, the margin of profit aimed at in certain lines of business will normally be very much higher than that which is expected in other lines. The pricing policy will, therefore, be much influenced by the degree of risk.

Further, the *conditions of production* under which the commodity is made will have a good deal of influence upon the price policy which can be followed. If production is carried on under conditions of increasing cost or diminishing returns, it would very obviously be folly to attempt to increase sales by keeping the price as low as possible. On the other hand, when production is carried on under conditions of decreasing cost or increasing returns, there may at times be a very definite gain in increasing volume of sales by means of a decrease in prices, so that larger aggregate net profits can be made, even though the profit per unit of goods sold is less than if higher prices had been maintained.

Also, the nature of the *demand* must be carefully considered. If a commodity is subject to an inelastic demand, changes in price may have no particular effect on the number of units which can be sold. On the other hand, if the demand is elastic a very nice problem of calculation may arise as to what price policy will yield the highest net returns. There is at all times this interplay of conditions of cost and conditions of demand.

¹ Adapted by permission from "Applied Business Finance," McGraw-Hill Book Company, Inc., 1929.

It must not be supposed, however, that the commonly stated economic theory to the effect that the selling price tends to settle at a point which represents the cost of production to the marginal producer, or to the most efficient producer of the goods, is literally true. This, no doubt, is a long-run tendency, but the theory applies to a static rather than a dynamic state of affairs. The business world, however, is most dynamic. Conditions constantly change. When the long run has arrived, a wholly new basis of costs has also been reached. There is haggling and bargaining and adjustment which cannot be reduced to any definite formulae.

The market phenomena of price frequently show extremely wide variations from any rules which the armchair theorist may have laid down, though a careful study of these principles is very valuable for purposes of guidance. At all times some goods are sold below the cost of production, whether voluntarily or involuntarily. Further, in certain lines of business there are probably occasions when all goods are being sold far in excess of their cost of production, due to psychological and other considerations. It is frequently possible to increase the sale of goods by increasing the price and appealing to the vanity or the fear of the customer. When prices were tending rapidly upward toward the end of the war period, many dealers increased their volume of sales, at enormous profits, by persuading customers that the price would rise still higher. On the other hand, when prices began to drop, there were many instances in which trade was lost altogether as a result of price reductions. The customers decided that if prices were dropping they would drop still further, and that goods might be purchased more profitably at some future time.

Such is the play and interplay of forces which appear at all stages of the business cycle and which vary in their effectiveness from industry to industry. In a measure it is true to say that the law of price is as variable as is human psychology. And, after all, it is the customer and not the producer who sets the price.

To sum up the matter very briefly, such considerations as the following must be carefully weighed when the seller puts a price on his goods:

1. What do the goods *cost* delivered to the customer, allowance having been made for all items of expense and a reasonable profit? As a general principle, no concern is justified in selling at a loss. Exceptions to this rule will be noted in a moment.

2. What does the *competitor* charge for similar goods, and what does it cost him to produce? Many a business has ruined itself by attempting to sell at a price made by a competitor who did not know his own costs of production. In certain well-established lines of industry it may be absolutely essential for a new seller to accept the price standards set by those already in the field. If so, his problem is greatly simplified.

3. The considerations just mentioned will enable the seller to determine whether he can afford to do business. After this point, it is essential to consider the customer and his needs. What are the conditions of *demand*? Can a sufficient amount of the goods be sold at a price necessary to enable the business to be carried on? It will be most important to study the demand, not only in a general way as to its elasticity or inelasticity, but also with

specific reference to the peculiarities of prospective purchasers. For example, what class of customers are to be appealed to? What is their prevailing psychology? What is their standard of living? What are their customs and prejudices?

Many a hopeful business has been wrecked by neglecting to make allowances for some of these psychological factors which have no relation whatever to questions of cost or of the abstract theories of demand and supply. The producer can by no means be sure that certain classes of customers will buy his goods, even though the price is right and even though apparently they might need goods similar to those he has for sale. There may be national, religious, racial, or political prejudices which will completely unbalance the most carefully laid plans that have failed to consider these intangible but most powerful elements in the situation.

4. Closely related to the foregoing consideration is the question of *quality and service*. Quality may be either tangible or intangible so far as it relates to the sale of a particular commodity. What people can be made to think of a product is frequently far more effective in influencing its selling price than the real quality as measured in terms of usefulness or durability. The appeal to the imagination is frequently the most effective appeal to the pocketbook. Particular individual services rendered in connection with the sale of the goods may enable a price to be secured which is very much out of line with the actual cost of production.

5. Naturally, there are very many other considerations to be borne in mind. Most of these, however, are in some way related to the foregoing.

a. It should, perhaps, be noted that certain types of seasonal goods will normally be sold at a price which is apparently very high as compared with the actual cost of production, due sometimes to unusual risks undertaken by the seller. The same consideration may apply in connection with highly "fashional" products.

b. Also, the customary or possible rate of turnover will sometimes markedly affect the price. Where the annual turnover of goods, from the nature of the case, must be very low, it frequently happens that a price is made and maintained which represents a good deal of insurance charged by the seller over and above all actual expenses.

c. Similarly if the customary terms of sale are long, the price must be increased in order to provide sufficient interest on capital invested in receivables as well as to insure the seller against the additional risks which result from the extension of longer credits.

Relation to Market Prices. Having made some of the analyses here indicated, the seller of goods must determine in his particular case whether he wishes to sell (a) below the market, (b) at the market, or (c) above the market. In the former case his aim will be to undercut competitors and make larger net returns through a small margin of profit on a larger volume of units sold. If the second policy is followed it will be necessary to adopt some method of differentiating the product from similar ones already on the market. This is the easiest method to follow, but may not lead to any particular degree of success unless the product is very vigorously pushed by advertising. When the conscious attempt is made to sell goods at a higher

price than is commanded by those of a similar quality now on the market, it is necessary to emphasize certain distinctive features. There must be something special about the goods which will attract the interest of the consumer, even though the actual quality is no better than could be secured at a lower price. In such cases advertising must be extensively used.

Upon the whole the business man in attempting to arrive at the most profitable price for his goods thinks more of consumers surplus, as the economist terms it, than of the mere interplay of demand and supply. He knows that there are many buyers who can, and will, pay a much higher price than could be secured from the mere marginal purchaser. He may, therefore, find it much more advantageous to appeal to these "intramarginal" customers until competition forces his prices downward.

When Is It Profitable to Sell below Cost? Obviously, no concern can for any length of time sell below cost and maintain its economic existence. However, there are always some producers who sell goods below cost. Some companies make a practice of always selling certain articles at a price which is insufficient to cover the expenses of production. At times it may even be highly advantageous to sell below cost, as the term is ordinarily understood. Some of the circumstances under which goods may be sold at a loss are as follows:

1. The producer *may not know his actual cost of production*. As a result of his eagerness to do business and sell a large quantity of goods, he may rapidly use up his capital without realizing his predicament until he fails. A surprisingly large proportion of all businesses are at some time or another in this class. It is a malady particularly common to the newly launched enterprise. Even in the prosperous year of 1926, there were 197,186 corporations which sold their goods or services at a loss. Probably several times this number of unincorporated enterprises were guilty of the same practice, and doubtless few of them were aware until their income tax returns were prepared that they were actually operating at a deficit.

2. When *new capital can be readily secured from a too credulous public*, it sometimes happens that a concern continues for years to sell its product at a loss. This has undoubtedly happened in the case of many of the metal mines, which are always "on the verge of making big profits."

3. Again, goods may be sold below cost as a result of *cut-throat competition*. This practice has been from time to time followed by powerful organizations with a view to crushing competitors. Millions of dollars have been lost in price-cutting campaigns of this sort, the ultimate result of which is usually an era of higher prices when competition has temporarily ceased.

4. Goods may be sold at a loss with a view to *developing prospective goodwill*. It would obviously be impossible for certain types of newly launched enterprises immediately to make a profit on the goods sold. They must wait until a sufficient volume is secured, and it would frequently be impossible to obtain this volume unless prices were kept at the point which will be ultimately profitable, but which at present makes it necessary for the producer to incur a loss. This policy may be a very necessary and wholly desirable one, provided the seller knows definitely what he is doing and can see clearly when and how profits will ultimately be made.

5. Some companies, again, consciously and purposely sell certain *minor products* at a loss with a view to *retaining the goodwill* of their customers. The situation may result from a gradual curtailment of certain lines of goods so that they are no longer profitably produced. It may be due to influence which has been exerted by salesmen who wish to cater to the particular whims of their customers. It is possible that certain low-priced and non-profitable articles are used as "leaders" in order to facilitate the sale of other goods.

Probably all cases of this sort which result in sale below cost of production are conscious attempts to develop goodwill. Each concern must be its own judge as to the wisdom of such a policy. Under such circumstances the losses incurred are regarded as a particular type of advertising. As a rule, however, the policy is a dangerous one and can very easily grow beyond all bounds.

6. Frequently, retailers sell certain articles far below cost merely to serve as "*leaders*" to induce other purchases to be made. This happens particularly during special sales when a few first-class articles are distributed among inferior goods of the same sort in order to attract buyers. Another example is furnished by the "1-cent sales" occasionally put on by the Rexall stores, that is, two articles are sold for the price of one, plus 1 cent. Such sales, of course, usually have a high advertising value, and they lead to the buying of additional products. They are particularly advantageous when prices are falling and trade is dull. They are best suited, however, to those retailers who control the source of supply of the particular goods, or who themselves manufacture the goods sold. They accomplish their results best when the very numerous array of articles not in the one cent sale is carefully brought to the buyer's attention.

7. Closely related to the foregoing is the policy sometimes followed of selling all articles of a given sort at a uniform price notwithstanding wide differences in size. Makers of different articles of apparel, particularly, have followed this practise, as a result of which the very small sizes may be sold at a profit while the larger sizes may even be handled at some slight loss. The theory is that the price fixed will be sufficient to assure a profit on the average item sold. Some companies maintain that it is much more convenient to handle the matter of sizes this way. Any such policy is generally wrong. It is, of course, easier to keep no cost records and to guess at the price. The only safe rule in cases of this sort is to let the price of each article cover its proper costs. When the chief cost of production is for material used, the uniform price policy will probably prove particularly unwise.

8. In the case of *by-products* the question is a mooted one, since it is sometimes very difficult to know what by-products actually cost. Some concerns, as previously mentioned, have even sold the main product below its true cost of production because of the very high returns which they have been able to gain on by-products. Such a policy is usually unwarranted. Also, in determining the price of by-products or joint products, the estimated separable expenses should at least be covered by the price received, and there should also be an allowance for material costs equal to that which would be received if the material were sold, or which would have to be paid if the goods were bought and devoted to similar uses.

9. It has sometimes been found profitable to *sell goods at a loss in one market*. Such instances are found only in international trade where tariff boundaries protect. It has been argued that because of the increased economies resulting from larger scale production certain types of manufacturing concerns have found it advantageous to produce goods in excess of the demand of the home market and to "dump" the surplus on foreign markets at a price lower than the unit costs of the entire product. The alleged justification for this practice, which is by no means so common as is ordinarily supposed, lies in the fact that by increasing the volume produced, unit costs of operation are lowered, but if no more goods are put on the home market the selling price will remain at the original level.

10. It happens in certain lines of industry that production cannot readily be evenly distributed throughout the day or throughout the year. In such cases overhead expenses continue whether goods are being actually produced or not. It may, therefore, be profitable in order to keep the plant in operation to sell goods made in the "off-peak" periods at a price which is only slightly higher than the prime costs, that is, the direct labor and material expenses which enter into the specific product.

The problem of *seasonal goods* is sometimes solved in this way to the benefit of all concerned. Also the practice is recognized and generally followed in the electric light and power business, in which special low rates are made to those who use current for power, or whose demand on the plant comes at a time when there is much excess capacity available. The power business and the off-peak business of electric lighting plants is very frequently billed at a rate per kilowatt-hour which is lower than the average cost of production per kilowatt-hour for all current sold. Yet, inasmuch as the additional sales necessitate no increased plant investment and practically no additional operating expense, except perhaps a little more fuel cost, it is obviously to the advantage of the company to sell current under these circumstances at a rate which will net a slight profit over and above the low additional cost which must be incurred to render the service.

11. It is rather interesting to note further that there are circumstances under which *by selling at a loss a company may reduce its losses*. It is common knowledge that in order to "break even" many factories must operate to at least 60 per cent of their capacity. The actual profits frequently cannot be made until the utilization of plant exceeds this ratio, these figures being used merely for purposes of illustration. This condition results from the fact that with a smaller volume of goods produced, the various supplementary costs, administration and office expenses, general supervision, depreciation, insurance, taxes, interest, and the like, are distributed over a much narrower number of units, thereby increasing the cost per unit. Even though the plant should practically cease operation, most of the expenses referred to would continue without abatement. It is obvious, therefore, that when a plant is being operated below the profit capacity, the *losses* may be *reduced* by selling goods for little more than the actual direct costs of producing those goods. Any margin thus gained will help in defraying the expenses which must be met whether the plant is operated or not. Extreme caution, however, is necessary lest the customer be led to think that the unprofitable

price is the fair price, which in more normal times he will expect to have continued.

12. In times of *rapidly falling prices* it is frequently the height of wisdom to sell for less than their cost goods *already produced*. Thus continued shrinkage of inventory values may be avoided and possible losses curtailed. Many a concern has been ruined as the result of its failure to recognize this important principle. The rule should be not to wait until financial necessities arise, but to take losses at once when prices are dropping precipitately.

13. The *actual or prospective drop in the demand* for a certain line of goods may lead the seller to dispose of a portion of his inventory at a loss even in normal times. Such a policy may not only prevent a greater future loss, but may also serve to unlock working capital already tied up in slow-moving inventory. Similarly, whenever stocks become antiquated they should be cleaned out, even at a sacrifice, in order to free the capital for other purposes. Profits can be made in business only when goods are sold and the investment is turned with reasonable rapidity. This situation explains many of the bargain sales which actually are bargains. The seller finds it more profitable to take a loss on certain articles in order to gain a greater profit elsewhere.

14. Finally, goods are frequently sold at a loss because of the *financial urgencies of the seller*, irrespective of general business conditions. He may have overstocked himself even though his line of goods is perfectly satisfactory. In order to raise working capital to meet his current bills he may be forced to sell a portion of his stock at a loss either direct to the consumer or to other dealers. The final step in this direction is frequently a receivership sale, though some sellers have been able by taking a severe loss to avoid bankruptcy.

Shall Prices Be Uniform? Many interesting questions might be raised regarding the problem of uniform prices and price discrimination. Uniform prices may mean many different things.

1. There may be uniformity as to all customers irrespective of their status or of the quantity of goods purchased.

2. The uniformity may extend only to all within a given class or group. For example, all retailers may be quoted a uniform price, while all wholesalers, without regard to the size of their purchases, may be given another rate. Such differences are commonly met with.

3. There may be uniformity as to territory supplied. The price may be the same for all customers of given class within an entire territory, or geographical distinctions may be recognized in arriving at the price. When the transportation costs are great there must naturally be such differences, or prices must be quoted f. o. b. the factory.

4. A uniform price policy may be followed with regard to the terms of sale, that is, all may be required to pay cash or, on the other hand, may be given an equal period of time within which to make payment. Any departure will naturally result in varying prices actually being paid by customers because of the cash discounts allowed for prompt payment.

5. Sometimes lack of uniformity results through the offering of special concessions for special services, for example, goods may be sold at a lower rate to the dealer who will take the full line of the seller instead of buying only one

product. Again, a special price may be made to those retailers who agree not to handle the goods of a competing producer.

6. Special off season prices are also offered to the purchaser in some industries, and seasonal datings are very common. Such practises lead to a further lack of uniformity.

Quantity Discount. The question of quantity discount is of a good deal of significance to the seller. This should not be confused with the cash discount nor with the *trade discount*. The latter is a device used primarily in order to conceal the actual purchase price of goods from the ultimate customer. Further it makes possible a uniform selling price of the product without actually fixing that price to the consumer, and is useful when sales are made at different prices to wholesalers and retailers.

The quantity discount is given on the assumption that large orders can be more profitably handled than small ones, and the actual discount should be carefully determined in view of actual savings which may result. In practise, it has frequently been found rather disastrous to offer quantity discounts because of the frequent abuses of the terms offered. When prices vary according to the quantity sold, it is possible that through cooperative purchasing or chain store purchases a situation may develop in which the retailer offers to the ultimate consumer a price which is as low as that which the wholesaler can offer to the retailer. The offer of quantity discounts to retailers also frequently leads to overbuying with very disastrous consequences. It is extremely important to outline a policy which will not cause mutual misunderstanding, and which will not result in unjust discrimination between various groups of purchasers. In order to avoid unpleasant difficulties, some sellers, therefore, refuse to give quantity discounts.

Price Concessions. Another interesting question is raised in connection with getting new business. Should special price concessions be made in order to attract new customers? Such a policy has sometimes been openly followed by the seller. More frequently the practise has been merely winked at, while salesmen have, within limits, followed their own pleasure in the matter, frequently offering special price inducements in order to increase their volume. Occasionally the salesman himself has deducted the concession allowed from his own commission. But, however the matter may be handled, this policy is almost certain to lead to difficulties and to cause misunderstandings. The practise is undignified and if generally known will reflect unfavorably upon the seller. Dissatisfaction will arise on the part of those customers who do not receive concessions. Further, if the practice is left more or less in the hands of the salesmen themselves, the possible evils are greatly multiplied because of the irregularities which inevitably arise. While there are possibly a few exceptions any such policy in most lines of business is wholly unsound and savors of the primitive method of arriving at market prices through direct bargaining between customer and seller. Price concessions may sometimes be justifiable in pushing new lines of goods with old customers. They should not ordinarily be given, however, merely to get new customers.

One Customer Only. Again, another interesting problem arises: Should the producer sell to only one customer or to a very small group? Much, of course, depends upon the nature of the business and the relation between the

buyer and seller. Obviously, the seller can afford to dispose of his goods at a lower price if his selling expenses are in this manner cut down. It is dangerous, however, to sell the entire output to one customer unless a very definite contract is made, subject to renewal under mutually satisfactory conditions, which will protect the interests of the seller.

In the meantime the contract should provide for some sliding scale arrangement whereby the price agreed upon might be subject to adjustment in accordance with the general trend of prices for a similar commodity. Otherwise a seller may be in danger of finding himself wholly in the power of the buyer who may force deliveries at unprofitable prices or may refuse to renew the contract after special investment has been made in order to meet his needs. The dangers to the seller are greatly increased if, as is frequently the case, he does not use his own name or brand when selling in large quantities to a limited number of purchasers. When no distinguishing marks are used, no goodwill or independent market for the product can possibly be developed.

Price Guaranties. Another important consideration has to do with the guaranty of the customer by the seller against decline in prices after orders are received or goods are sold. Such guaranties are very common in some lines of industry and may be made under any one of the following conditions:

1. The guaranty against decline may hold good until the date of shipment of an order which has been received for future delivery.
2. The guaranty may extend until the date of delivery.
3. The guaranty may extend to a fixed date.
4. The guaranty may cover the period which must normally elapse until goods are sold.

5. The guaranty may sometimes refer, not to the selling price of the purchaser, but to the future selling price of the one who gives the guaranty.

Ordinarily this guaranty means that when a manufacturer disposes of a commodity at a stated price he obligates himself in the event of a decline in price to rebate to the purchaser, at some future date agreed upon, the difference between the stated price at the date of sale and the reduced price at which the purchaser may be obliged to resell between the date of sale and the agreed-upon date of settlement. When the practice is confined merely to a guaranty which shall end with the date of shipment or of delivery, no serious problems arise. When the guaranty extends beyond this date, however, it is obvious that the responsibilities of the guarantor may become of major significance.

Some of the customary arguments alleged in favor of the price guaranty practice are as follows:

1. Such guaranties are, from the manufacturer's standpoint desirable because: (a) Sales are increased thereby. (b) Seasonal fluctuations can be avoided, due to the advance orders which are secured. (c) Goods can be shipped as soon as finished, thus avoiding warehouse expenses. (d) Larger orders can thus be secured. (e) Payment is frequently made at an earlier date than would otherwise be the case. (f) Cancellations are prevented in a falling market. (g) Market prices in general tend to be stabilized by this practice.

2. The arguments favoring the practice from the wholesaler's or retailer's point of view are such as follows: (a) The guaranty protects them against

loss due to a falling market. (b) It encourages them to place their orders early and thus avoid delays in shipment. (c) It permits the handling of goods by the wholesaler on a smaller margin of profit because of the reduction in risk. This makes possible a lower price to the consumer.

Some of the opposing arguments are as follows: (a) It is unfair to the manufacturer to be expected to protect the wholesaler or retailer in this manner. Since the manufacturer himself is not protected, he cannot afford to assume the risk for those who purchase from him. (b) The practice may tend to keep prices high in a wholly artificial manner. (c) The manufacturer may, as a result of this practice, be encouraged to produce in excess of the probable demand for goods on the part of the ultimate consumer. Due to the readier sales to the middleman he may be wholly misled as to the actual market conditions. (d) The middleman, in turn, may recklessly overbuy because of the carelessness which results from price guaranties.

Obviously there are many sides to the problem, and it is interesting to find that there is wide disagreement on the question among manufacturers, even when engaged in the same line of industry. From the seller's point of view, the policy of guaranteeing against price declines is probably most feasible when the raw material cost is a very small part of the producer's selling price. Under such circumstances the fluctuations in market price will probably be less rapid or violent. However, the customer in such cases would have least need of the guaranty. On the other hand, it has been maintained by some manufacturers that prices should be guaranteed to customers in those products in which the fluctuation will probably be most rapid, as for example, in those commodities in which the cost of raw material plays a very important part. Naturally, the buyer of goods would particularly favor a guaranty under these circumstances.

No definite rules can be laid down with reference to this most interesting problem. Much will depend upon the nature and customs of the business itself, the type of customers served, and the usual terms of sale in the trade. The practice may possibly prevent violent price fluctuations in certain lines of trade. It may also lead to a more even distribution of orders throughout the year. In such cases, the policy would seem to be wholly desirable. In times of uncertainty, however, many new elements enter into the situation. If mutual benefit is received by buyer and seller, the practice justifies itself. If, on the other hand, the risks are all on the side of the guarantor, it will obviously be necessary for him to increase his prices in order to insure himself against losses which may be incurred through his guaranty to the buyer.

Price Maintenance. Briefly stated, price maintenance refers to the policy sometimes followed by the manufacturer of placing restrictions upon the price at which a purchaser may resell an article which is identified by some brand, copyright, trade-mark, or the like. Formerly this practice could not extend far, inasmuch as probably the greater part of all goods sold was not identified in this manner. Recently, however, trade-marked and package goods have been rapidly increasing.

From the manufacturer's point of view such price protection is perhaps sometimes needed in order to prevent the reselling of his goods at a low price for advertising purposes. Frequently, large purchasers have bought branded

goods in quantities and have sold them at a low price with a view to injuring the business of the producer. The manufacturer also alleges that the fixing of a uniform price to be charged the ultimate consumer prevents overcharging and much ill will, which might result from the lack of a uniform price on the same branded goods. There is, of course, much to be said in favor of this contention.

The law dealing with the question of price maintenance is yet somewhat uncertain, inasmuch as many conflicting decisions have been rendered. Probably, however, there has been far too much excitement about the problem. Obviously, if trade-marked goods are not found by the customer to be satisfactory and worth the money which he pays for them, he will buy in preference a non-branded article or the advertised goods of some other producer. It would seem, therefore, that so far as the public interest is concerned, the question might in most cases be left to work out its own solution under competitive conditions.

Another interesting development is that of the "*open-price*" association, the primary purpose of which is to assure the maintenance of uniform prices within a given industry. The single price is arrived at through open discussion and interchange of information without any attempted coercion. To the extent that prices can be stabilized at a reasonable level through such activity, the open-price association is to be commended. It may serve a particularly useful function in disseminating helpful information regarding costs of operation and methods of business among the producers in a given industry.

CHAPTER V

CHOICE OF MARKETING CHANNELS

BY GORTON JAMES, *Vice President, The Thompson and Lichtner Company*

Choice of distribution channels and methods depends primarily on three factors: (1) *cost*, (2) *competitive strategy*, (3) *volume*—sometimes contradictory. Hence the marketing difficulties of many concerns whose executives have considered only one of the three factors in shaping their policies.

Competitive strategy may demand, for temporary periods, sales below costs or distribution expenses out of all proportion to theoretical selling efficiencies. But trouble grows rapidly in such cases unless the executive recognizes the dangerous course he is pursuing, keeps a close eye on his controls, and does not relax his vigilance as long as the battle is on.

For a long time policy, however, it is doubtful if sales below cost can be justified. This statement is made in the face of the existence of such policies—for instance, the carrying of "loss leaders" for the supposed purpose of attracting customers—actually in force in the sales programs of some of the biggest and best-known independent and chain retailers, and manufacturers.

In the final analysis the plan of marketing is best that will produce that volume which, at the cost of attaining it, will yield the greatest net profits in the long run. The optimum volume is seldom the greatest attainable volume and the optimum marketing cost is seldom the lowest possible cost.

As an example of sales below cost as competitive strategy there is a well known chain which has always offered one leader below the cost of manufacturing and distributing it. This policy was an important factor in building up the reputation of the firm, at the outset, as a retail organization which could deliver dependable goods at a surprisingly low price. The policy has been maintained to serve as proof of the "buying power" of the concern.

As it happens the chain has not always had to carry the loss from this policy itself, even though it stood ready to do this as part of its advertising expense. Manufacturers' salesmen, on commission, more interested in sales than profits, have noted the retail selling price of this article and, with a naive faith that manufacturing costs can be reduced to any figure if the boss will permit, have reasoned that their competitor must have reduced his costs and selling price in order to get the business. On such reasoning, salesmen have induced several companies at times to offer this product to this chain at such figures as to take the loss off the shoulders of the chain. The manufacturers explained that by this eleemosynary act they were "spreading overhead" or "keeping the factory running." As a permanent policy, however, that is a dangerous plan. Some of those suppliers have entirely

gone out of existence and perhaps that particular trade will "return to normalcy," but in the meantime prices for that article have dropped below the costs of manufacture for everyone.

Thus, this one chain with this policy on one item has driven one entire section of an industry into chaos and has made itself heartily hated by all in that industry. Whether its policy will prove to have been good for its own business in the long run remains to be seen. So far it has built up for itself a reputation among its customers of great buying power and undoubtedly has quickened the growth of its business. This case is cited because it is an exception, and a prominent one, to the usual experience of companies who sell below cost as a regular policy. It is a case where one of our leading retailers has considered that selling below cost has been justified by competitive strategy.

The Balance between Market and Product. The choice of method of marketing a given product depends on a process which is the reverse of "merchandising." Merchandising consists of selecting, designing, and presenting the product to fit the demand. Each element of a product—quality, appearance, usefulness, price—appeals to or repels the prospective buyer. When one such element is newly emphasized as against another in advertising and selling, new prospects will be added to the market and others lost.

If an automobile is built with special reference to beauty of line, it will appeal to a different section of the public than if it is built with mechanical perfection as the primary offering. Each slight change in model will attract a new group of people and thus shift the market slightly. Successful marketing, therefore, requires not only the adjustment of the product to fit the market but its reverse—the recognition of just what part of the public has potential interest in the given product.

It is not enough to say that most people will buy canned peas when fresh peas are out of season. Some like them sweet, others want them peppery. Some like them large and mushy, others want them small and crisp. Some like them in big cans, others prefer small cans. Some like bright wrappers, other associate bright wrappers with poor quality. The two problems which are least understood today in the marketing of any one of these varieties of canned peas is how to find the persons who like that particular variety, and how to offer it only to them without wasting sales efforts on the others.

Then comes the method of presentation. Some will buy because they always try the latest thing—want to be up to date; others cannot be induced to buy until at least three of their best friends have spoken with enthusiasm of the new product, regardless of the amount of advertising appeal. Some buy a few times and then change to the next new competing product; others are slow to become customers but when caught stay faithful as long as the product is offered. Some demand changes if they are to be kept as customers, others stop being customers if a change is made.

Each change in product, and in its presentation, affects favorably or unfavorably various sectional groups within the market. Recognition of these facts permits sound approach to the first questions in marketing a product. Who are the potential customers? Where are they? Why might

they be interested? Which elements of the product, appeal to which groups in the potential market? And finally, what kind of selling people can reach them best? Which type of retail outlet and which sales technique will sell the most of the products to ultimate consumers at the least cost in the long run?

Elements of Consumer Preference. Professor J. L. Palmer of the University of Chicago made some pertinent remarks regarding such analysis of the consumers which sketch the picture very successfully:¹

Information on family spending habits is so scarce as to require no comment and the question as to what the consumer of today is interested in when he buys commodities is one on which we can but entertain difference of opinion. Some say that style and beauty are the important thing, and that price has become secondary. By others it is pointed out that quality is all-important, that the consumer of today, with his higher purchasing power, demands better merchandise. But the manufacturer of men's quality clothing points out that it is becoming more difficult to sell high-priced clothing, and that men in increasing numbers are satisfied to buy suits in the lower price ranges. The query is also raised as to why installment selling, and the chain store with its "cash-and-carry" appeal, should have grown so rapidly during a period in which the purchasing power of the consumer has been rising. But as evidence of the waning interest of the consumer in price, cases are cited of remarkably profitable sales campaigns based upon a style or service appeal, in which products were sold at admittedly high prices. Out of this maze of seemingly conflicting views about the consumer the problem of the individual concern is to discover what combination of appeals will produce the best results in the marketing of its product. It is probably safe in operating upon one basic assumption, *i.e.*, that the great majority of buyers are interested primarily in value. Extremely wealthy buyers and purchasers of prestige and gift merchandise may in some measure be exceptions. Concerns may often proceed upon a second assumption, *i.e.*, that the consumer is usually a poor judge of value. It is this fact, coupled with the ingeniousness of the seller in manipulating his product and advertising it, rather than any declining interest of the consumer in value, that accounts for most successful sales campaigns in which the intrinsic worth of the commodity is more or less disregarded.

Whether, along with good value, consumers are also interested in style, color, service, quality, etc., is a question of fact in the individual case and the individual manufacturer will do well to find out the facts with reference to his own product. Style and color, while of obvious value in selling women's apparel, are relatively unimportant in marketing men's clothing. Elaborate service, while the main patronage appeal of certain types of department stores, has not in recent years been a suitable basis upon which to build a large retail grocery business. High quality, while generally desired in the purchase of some commodities, is often not desired in the purchase of others. If for any reason at all substantial numbers of people decide they do not want to spend large parts of their incomes on clothing, shoes or expensive foods the only recourse for the manufacturer is to try to dissuade them from their views or to bring his product within the popular price range.

If it is true that the purchasing power of consumers has been rising in recent years it is equally true and perhaps more significant that their spending opportunity has been expanding at a more rapid rate. It is at least conceiv-

¹ PALMER, J. L., Professor of Marketing, University of Chicago, Marketing Executive' Series, No. 66, American Management Association.

able that the consumer is finding it more difficult than ever to satisfy his desire for commodities and that as a consequence he is buying with just as much discrimination and with just as great emphasis on value as ever before. Many, if not most, of the spectacular merchandising successes of the past decade involving all sorts of products—groceries, drugs, automobiles, household supplies and appliances, radio—stand as evidence of the soundness of the proposition that the consumer is interested first of all in value—getting his money's worth. His attitude toward style, color, service, and quality in individual products has been shifting about in the course of time, to the advantage of concerns which have closely followed trends and have adapted themselves to them, and to the great discomfiture of those which have not done so.

The following proposition should stand out in any discussion of the consumer as a buyer:

1. The starting point of every sales campaign is the consumer.
 - a. Permanent sales success can be realized only when one's product and method of selling are in every respect adapted to consumers' desires and habits.
 - b. Adaptation can be effected only when all pertinent facts about consumers are known.

2. Facts about consumers, though they have been greatly improved in recent years, are still far from adequate to suit the purposes of most manufacturers. They can be made adequate only through painstaking research carried on by the manufacturer, the industry of which the manufacturer is a part (especially important when the problem is to sell a product rather than a brand) and by outside agencies such as the government, publishing organizations and other miscellaneous research agencies.

The "Bell-shaped Curves" of Demand. The problem of finding true potential customers can be better understood if the fact that the statistical demand curve always takes the shape of a bell-shaped probability curve. For instance, when all sizes of shoes worn by a large number of men are plotted, the curve looks like Fig. 1. (The height represents the number of persons whose feet are the size directly below any given point on the curve.)

Most men would have feet of the intermediate sizes, at the highest points on the curve, but decreasing proportions would be found to have feet bigger or smaller than those middle sizes until we reach the giants and dwarfs who have feet entirely outside the range of regularly manufactured sizes.

This distribution of demand is true both of lengths and of widths, but the variations are much less in widths, so that the curve is higher and narrower than the curve for lengths. More persons in the same group would have the same width than would have the same length size of feet. (See Fig. 2.)

Both of these curves should be taken into consideration in merchandising—in deciding what to make. A striking illustration of a failure to take all the

FIG. 1.

Widths
FIG. 2.

facts into consideration on the distribution of shoe sizes and widths occurred in supplying the United States troops during the World War.

Army boots by millions were turned out on the standard schedule of foot sizes which shoe manufacturers by experience know the men of this country to need. But the constant "foot work" of army drill, for these many men who were called from office desks of civil life, resulted in spreading their feet, and shifted the actual curve of widths which were needed perceptibly to the right. As a result a shortage of the large-width shoes began to develop while there was an unaccountable surplus of the small widths. Only an intensive manufacturing drive on wider boots saved the situation from becoming serious.

Price Curves. The fact regarding these bell-shaped curves which concerns marketing, rather than merchandising, is that price range and quality demands also follow the same law. If the prices paid for the shoes now on the men of the country could be plotted the curve would look the same. (See Fig. 3.)

There is a range of intermediate-price shoes which satisfies the great masses. But there are some who will not, or cannot, pay as much—they will buy the cheapest shoes they can find. Others will pay more than the masses.

FIG. 3.

FIG. 4.

Quality Curves. Likewise quality is looked for and demanded by people in accordance with our bell-shaped curve. The great mass market does not demand high quality but refuses poor quality. A few persons, relatively, insist on higher quality. Another minority is content with substandard quality if it is cheap. (See Fig. 4.)

It is not necessarily because people are not able to afford the prices of higher quality that the majority of them are in the medium group; relatively few people appreciate refinements of quality in more than a few articles. A mechanic appreciates and demands a high-quality motor in his automobile but may not recognize the difference between good average coffee and the high-quality beverage.

Members of the clothing and woolen industries recognize and demand for themselves the best wools and worsteds. The rest of us do not readily recognize why one suit should cost \$22.50, another \$50.00, and another \$90.00; and if the \$50.00 has a pleasing pattern we may take it, feeling that it is neither dear nor cheap because it is in the middle price range, never know the difference, and be happy in our ignorance.

But a producer should not accept the popular notion that the *high-quality* demand and the *high-price* demand are synonymous. Much "waste in dis-

tribution" arises from this fallacy. A substantial portion of the high-price demand is such from motives of "swank." Cheap goods dressed up in brilliant surfaces will go better with that group than real quality unobtrusively offered. A person operating in the high-price field should recognize the difference between swank and quality seekers and look for some measure of the relative proportions of the two elements in his market. Note the different shapes of the two elements within the bell-shaped curve of incomes. Figure 5 indicates the area of the high-price market in the general price curve while Fig. 6 shows the position of the high-quality seekers in relation to the whole. In both diagrams the shaded areas are exaggerated in relative size so that their shape may be made clear.

It is important to keep in mind that the high-quality group, even that part of it which is able and willing to pay any price necessary to secure high quality, demands value for price. It knows the difference. And probably more than half of the potential high-quality market is not in the high-income group; it buys the higher quality merchandise because it believes it is more economical to do so, or because it indulges in a special "hobby" or pleasure

FIG. 5.

FIG. 6

which must be balanced by a special economy elsewhere in the budget.

The average smoker does not enjoy a corona-corona. The great masses of our people would not like really high-grade coffee. It would be a mistake, even if it were possible, to offer goods of high quality to the general public on a mass basis and mass appeal. Fortunately, it is not usually possible; the supply of top quality product in most cases is limited so that it would be physically impossible to sell it on a mass scale. When "everyone" hears of and calls for a new, especially high-quality cigar the makers must either throw overboard their standards of selection from the crop, use middle-quality tobacco and reduce the quality, or else turn a deaf ear to the demand. The result is usually self-adjusting. If they maintain quality the masses do not find the product "worth the price" and it becomes reserved for the connoisseurs. If they do lower quality, they enter the mass group with median quality and again a balance is struck. Cigar experts can name different brands of cigars which have followed each of these courses. They can also name others that have tried to straddle, who have gone out of business probably blaming the United States tariff.

Steps in Choosing Marketing Channels. An intelligent start cannot be made in choosing the channels for marketing a product until the location, the size and the nature of the potential consumer market is thus determined.

Selling through channels not keyed to reach the right final market has dissipated or nullified much selling effort on the part of producers. The balance must be struck between the product in all its details, and its potential market. Not only geographical location of the market but its location on each of the bell-shaped curves of consumer preference should be known before considering the channels through which the market is to be reached.

The question is, given the goal, Which is the best route to take to it? Too many have started at the producers' end and asked, Which is the easiest road away from here? (disregarding whether it leads in the direction of a good potential market or not). In short, beware of the lure of immediate big sales to a distributor. It is the producer's own business to be sure that there is a real and permanent market beyond that distributor. Furthermore, permanent business is usually built up slowly.

Work Backward. With distribution in its present chaotic state, dependable results can more frequently be obtained by working backward from the consumer rather than forward from the producer. Whether to sell, for instance, to a chain store depends more on whether that chain is the best calculated to reach that portion of the market having the greatest potential interest, rather than on whether the chain will give the producer a bigger order at the outset.

The method of working backwards is contrary to general current practice, but it will be found sound by those who use it. It frequently results, however, in radical changes in present choices of channel. On the other hand, were it generally applied, this method of choice might have a helpful influence towards reducing the bumps of the business cycle. Associated with every depression (if not responsible for it) is the clogging of distribution channels. The public does not vary its rates of buying to anywhere near the degree that producers find their rates of selling to vary. For instance in one of the months of 1930 a check-up was made of department store operations in an eastern city. It was discovered that while the stores' monthly sales had fallen off 6 per cent the purchases of the same stores were off 40 per cent.

The difference in degree of variation is caused by imperfect flow through the distributive channels so that minor changes in current consumer buying are greatly magnified when they are reflected back to the original sources. The solution, so far as there can be one, lies in choosing those marketing channels in which the flow will be most free.

The variation in the rate of flow within distribution channels from the source to final consumers may work either way. The sudden growth of chain stores for instance caused an unnaturally rapid call for goods to stock the new stores. Manufacturers have mistaken such sales for actual consumption. One manufacturer got into difficulties from such a mistake even though it arose from a chain of retail stores which he owned and operated himself. The increased rate of manufacture needed to fill his own retail shelves as he opened up new stores, was accepted by the production department as the new normal rate from the retail chain. When the process of opening new stores was completed and there was call only for replacement stocks on actual sales to the public there was a disastrous cut in production orders which found the factory overstaffed and overequipped.

This small sized experience within one organization took place on a large scale throughout many industries during the period of rapid expansion of chain stores. If the manufacturers had watched sales to final consumers instead of initial sales to distributors they would not have got caught with such widespread overcapacity as was discovered in 1930.

The producer may get his goods sold quickly if he can get a distributor to buy them and put them on his shelves; but he will not be called upon for a repeat order as quickly, nor in as great volume in the long run, if those goods do not move readily off those shelves to the consumer. The flow from the far end in the long run is more important than the immediate order at the source. Therefore, *work backwards*.

Advertising to the Consumer. Working backwards results moreover in a radically changed attitude toward advertising. Today a large proportion of so called "national advertising" of consumer goods is aimed at the retailer. If it is addressed to the final consumer at all, it is frequently designed for the purpose of forcing the retailer to carry the line. The real effort is focused on the distributor rather than the consumer.

Advertising specialists have already recognized that the power of the direct appeal to customers is greater in the long run than advertising directed over their shoulder at the retailers or jobbers. They are using such direct appeal copy in many newspaper and car-card advertisements but they encounter resistance on the part of the advertisers. Several selling campaigns have been weakened because producers have paid "lip service" to direct appeal advertising but have not shaped the balance of their selling efforts on the same principle. Such lack of coordinated marketing has often weakened the results of first-class work of both the selling and the advertising executives. Advertising and the activities of the sales department are most effective when they are geared to the same basic principles and their programs meshed throughout to run towards an identical goal by the same route. Unfortunately such coordination is seldom fully achieved, usually because the organizational set-up fails to unify the control of both activities.

Consumer Preference. In choosing the methods best calculated to market a given product, then, the first step is to analyze the final market. Consumer reaction to the product is to be ascertained. The questions for which answers are needed are: Which elements in the product appeal; which cause hesitation; which generate sales resistance? And why?

The survey necessary to get at such information requires trained observers. Probably more marketing programs fail because of inadequate or unscientific consumer preference study than because of any other one step in their development. It is not a matter which can be determined by sending out school children with opinion questionnaires to ring door bells. Opinions of persons on hypothetical questions have proved worse than worthless as foundations for marketing programs. One of the large nationally known manufacturers is at present in financial difficulties because a production and selling program was built on a consumer survey in which thousands of individuals were asked which one of a list of competing products he or she would buy if in the market. The answers proved that the biggest advertiser was best remembered. The trouble came from the fact that these potential consumers and others like

them do not necessarily buy the brand whose name they remember first. The company received a severe jolt when it discovered that fact.

The answer to problems of consumer preference is better contained in the records of actual purchases by consumers than in people's opinions. The opinion does not mean a sale. Ten thousand opinions do not add anything except a multiplication of the error. Why the purchases were made, what points were the contributing factors, are questions which require psychologists to answer. The purchasers themselves may not realize or acknowledge the true deciding factors. In short, consumer preference surveys call for the most skillful fact finding technique of any kind of market research, and should be undertaken only by experienced observers.

The only facts that can be entirely depended upon as indicators of consumer preference are actual sales. There are usually records of sales of products which are already on the market. It is not the gross volume, but the kind of sales and the kind of people who were purchasers that tell the tale. Detailed analysis of the distribution of sales gives light on important factors of consumer preference. Where the buyers come from, or which advertisement brought them in often gives the clue as to why they bought—a more reliable clue in many cases than their own statements.

A new product however does not have sales records. Any estimate of its market is, therefore, a guess and should be used as such. Dependable facts can come only from actual sales. In general, therefore, new products or old products through new channels should be marketed experimentally, and gradually before large operations are planned.

Trial and Error Method of Building Sales Programs. Not only are the facts of consumer preference needed in order to shape the advertising appeal but the facts regarding the type of selling best calculated to reach those consumers are needed for the selection of channels. Who best can sell the product, and by what method, depends on what are the deciding favorable and unfavorable factors in the reactions of the consumers. When it is known what kind of people can be made to buy, and under what circumstances, then and not until then, can the producer decide which kind of retailing will best sell his product. That decision involves finding the selling technique which most effectively moves the goods.

Types of Retailing and the Markets They Serve. When one has located, both geographically and on his bell-shaped curves of demand, the potential customers for his product, the next question is how best to sell these potential customers. How can they be told about the product and how can they be induced to buy? These are two questions which are mutually dependent. They cannot be effectively answered separately by an advertising manager and a sales manager. Let us run rapidly through the most common methods of retailing, making note of the special characteristics which must be considered:—

Stores Granting Credit and Making Deliveries. The right-hand half of the bell-shaped curve of the market, that is the higher priced end of the market, furnishes most of the customers for credit and delivery stores. More specifically they get the business of people who are too busy or not enough interested to "shop" for their purchases. They also attract people

who seek advice on their selections. Retailers who act as expert buyers for their customers can secure a loyal clientele which will stick regardless of the lesser price variations between those stores and their competitors. They may even boldly maintain their general price level above their competitors' in certain instances and still keep their customers. It is not the price that primarily counts since the customers are mostly from the top half of the income curve and the demand is for top-half quality products.

Food stores of this class receive a large portion of their orders by telephone. They are not good outlets for products whose principal appeal is price or a distinctive package. They are not good outlets for cheap lines or low-quality lines although they may sell a relatively small number of such lines quite successfully as side issues to their regular lines.

Furniture stores, on the other hand, necessarily do a credit and delivery business whether they are high-quality or low-quality outlets. Thus the generalization in the first paragraph is strictly limited in its application, although it applies to more than a majority of the retail credit and delivery stores.

Stores of this general class represent the oldest form of present-day retailing. As a result they are more varied in their characteristics than any other group. There are old fashioned stores with strong clienteles. They will probably continue to be dependable outlets for the types of products they carry as long as their present proprietors continue their active interest.

There are other old-fashioned stores which have "gone to seed." It is this section more than any other which has felt the inroads of the chain stores.

There are up-to-date stores run by live merchants, which can compete successfully with any or all chains. Their sales costs may be higher than those of the chains but their market is more certain and secure.

Cash-and-carry-stores are principally in chains but many independents are run on that basis. The appeal is essentially a price appeal. The justification claimed is that cash and carry retailing saves the retailer so much money the store can afford to quote lower prices. The facts that credit losses need not run over 1 per cent, and in the best-managed stores perhaps not over one-fourth of 1 per cent, and that delivery costs on a good business within a restricted area may be relatively small, belie the claims and force such stores onto a price basis in their buying. The result has been a healthy one for retailing because closer attention to prices has drawn attention to many wastes which have grown up in the older forms of distribution. The price showings of cash and carry stores have depended primarily on the elimination of marketing wastes and on close buying rather than on the fact that they do a cash-and-carry business.

Contrary to many popular statements, the chains do not cater to, nor have they marketed successfully to, the lower groups in the bell-shaped curve of income classifications. Poor people are dependent on credit. They will not pay chain-store prices which are frankly median prices, on good dependable median quality goods. Cheap goods for people of low income are not generally reaching their best market when they are sold from chain stores. (Specific exceptions to this general statement are granted.)

Whether *credit* should be extended to a customer or not and how to get the money for the sale if the customer does not pay up—those are retail store management problems. They may not directly affect the producer unless he elects to do his own retailing. But the terms on which a product is to be sold may have a large bearing on its acceptance by consumers. It is very doubtful, for instance, if the American public would buy automobiles at the rate it does if a majority of buyers were not permitted to pay for their cars at leisure. The installment method of selling at retail is of such consequence to the General Motors Corporation that it has organized the General Motors Acceptance Corporation to finance installment sales for its retailers.

The question of *delivery* of goods again may seem to be a retail problem quite outside the interest of the producer, but in the Boston Market a few years ago, after a bitter trade war, it was decided that delivered milk was worth 4 cents a quart more to the consumer than the same milk in the same size bottles sold in cash-and-carry stores. That 4 cents is of great consequence; it represents two different markets neither of which would be adequately reached were milk not offered both ways. It is usually folly to offer expensive food products as regular items in stores which do not deliver.

The retailing methods of the stores through which goods are to be marketed, therefore, are of consequence to the producer who desires to pick his channels of distribution effectively.

Small Merchants. Merchants doing from \$3,000 to \$25,000 gross business a year have a definite place in the distribution world. No retail agencies are better fitted to handle the distribution of items on the lower slopes of the price and quality curves to the lower slope of income groups. In localities where these stores are to be found, no other types of store are usually able to exist and compete with them successfully.

By Robots or Vending Machines. Any standardized article to be sold to mass markets in the lower half of the income curve, which can be packed or delivered in a standard package at a price represented by a coin in common circulation, which does not require special handling or storing, which will not spoil rapidly, which does not call for consumer selection, can be sold from a vending machine. Public acceptance of the product at the price asked must be assumed. Demand, therefore, must be adequately stimulated prior to offering in a vending machine.

Mail-order Selling. Articles of proven or dependable nature, accepted "national brands," goods whose nature may be adequately described in terms of known standards, goods made by manufacturers of established reputation, in short, goods which the purchaser feels can safely be bought without seeing, by description only—such goods can be sold by mail. The market to which they can be sold is almost entirely included within the middle-income groups. Economically-minded people, and people who are not satisfied with the retail stores in their marketing area are potential mail-order customers, provided they believe that they are thereby getting those goods at a lower price than they would otherwise have to pay. Thus, the lists of goods which can be sold by mail are restricted and their markets strictly limited. Incidentally, selling by mail can be done more cheaply the larger the volume. Mass selling makes possible factory efficiencies in handling mail and making shipments.

Two independent mail distributors have grown to such large sizes that their own names stand, within limits, as the guarantee of their products, thus greatly enlarging the list of products which they can sell. Even they, however, have restricted markets which have become still more restricted since good roads, automobiles, and more leisure have made it possible for rural dwellers to shop in large centers.

Pushed by the financial world ever to expand their sales, however, and believing the limits of the mail-order business under present conditions reached, both of these large companies have sought the required increase of gross business through opening chains of local general stores.

Producers seeking marketing outlets should recognize the fact that the type of goods best sold through general stores is not the same as those best sold by mail. There is some overlap, to be sure, in the list of goods which may be sold either way, but the producer choosing his marketing channel by the process of working backwards should ascertain whether his goods are to be sold by mail or from retail counters.

If a given product is saleable by mail there remains the choice of whether it can be sold best through a mail-order house or direct. The answer depends, first, on whether or not that product needs the added guarantee of the name of the large mail-order house and, second, whether or not the sales, if handled direct, would be large enough to carry the overhead, the advertising, and the expense of the necessary organization.

Canvassers. Some items must be shown and explained before sale is possible. Printed words are not enough. Taking the goods around to show to potential buyers costs more, to be sure, but on items which require showing or explaining, it is effective. So much so that two well known and highly successful marketing programs have been built around house-to-house canvassing. The successes led to an increase in the use of such selling and the development of direct-to-consumer wagon selling some of which is apparently successful but much of which has defeated its own purpose by pestering the housewife too far. There are limits to the amount of house-to-house selling which any area will stand.

Choice of Type of Outlet. Through what kind of store a given product can best be sold next requires study. It is not to be answered simply by finding out what class of stores usually handle the given line of goods. There is almost no general class of stores which can be designated that would not contain individual stores somewhere in the United States selling any known product, sold anywhere at retail.

That condition has probably been brought about by the common belief that the more outlets are used the more sales will be made. Unfortunately that is not true for many classes of goods. Furthermore, distribution costs increase rapidly as more outlets are added. It does not pay to add outlets unless they produce a profit for the supplier. Products which require any of the special techniques of selling may even experience decreases of total sales when every Tom, Dick, and Harry offers them.

Moreover, there is a constant shifting of the flow. The mass flow of books, for instance, may at one time be through book stores; at another, through department stores; and at still another time, through drug stores. Shifts

of popular fancy, changes in the sales technique or layout of one or another class of stores, changes taking place in jobbing are each adding to the rate of flux. One must keep pace with what is going on or he gets hopelessly behind. The distributor who is one jump ahead of the mass, or who leads in bringing about a change, is the one who gets the reward in profits (unless he guesses wrong and gets his reward in red figures).

People buy in masses. All other factors equal, it is cheaper to distribute and find the customers for a given product through the channels regularly used for the mass movement of like goods, than to establish special channels for the single product. But people buy many things and in many different kinds of stores and consequently there are occasional opportunities to reach new markets by utilizing the distribution machinery of entirely different products or by making use of different types of outlets than those regularly used for competing products. In other words, it often pays to experiment; it certainly pays to keep alert.

The Various Kinds of Retail Stores. There are estimated to be about 1,500,000 retail outlets of all kinds in the United States not including at least another half million of little retail stands—roadside vendors, front-parlor shops, shoe-shine stands, and the like—all doing retail business. Of the 1½ million about three-fourths are independent retailers and they probably do about 55 per cent of all the business.¹

Having decided what methods of presentation will best reach the potential market for a given product, the next question to ask is which specific types of retail stores to use (unless, of course, it has been decided to sell by mail or by canvasser). There follows a list of the various types of retail outlets arranged by the classifications used in the questionnaires of the census of distribution:

Automotive group.

Motor vehicle dealers (new and trade-in but not including used-car establishments).

Accessories, tires, and batteries.

Filling stations.

Motorcycles, bicycles, and supplies dealers.

Garages, repair shops, gas, and oil.

Food group.

Bakeries.

Candy and confectionery stores.

Dairy products, eggs, and poultry.

Delicatessen stores.

Fruits and vegetables.

Grocery stores.

Grocery stores with fresh meat departments.

Meat markets (including fish).

Milk dealers.

Other food stores.

General merchandise group.

Department stores.

General stores.

Dry-goods stores.

Variety, five-and-ten, and to-a-dollar stores.

¹ Estimate by Prof. Paul H. Nystrom of Columbia University.

Apparel group.

Men's and boys' clothing and furnishings (including hats and caps).

Women's and children's ready to wear and accessories.

Millinery.

Specialty shops.

Men's, women's, and children's clothing stores.

Other apparel and accessories.

Shoes (men's, women's, and children's).

Lumber and building group.

Lumber and building materials (exclusively retail).

Hardware stores.

Electrical shops.

Heating and plumbing shops.

Paint and glass stores.

Furniture and household appliances.

Floor coverings, draperies, curtains, and upholstery.

Furniture stores.

Household appliance stores.

Other furnishings and appliances.

China, glassware, tinware, aluminumware.

Restaurants and eating places.

Restaurants.

Cafeterias.

Lunch rooms.

Lunch counters and refreshment stands.

Fountains, soft-drink places.

Other retail stores.

Book stores.

Cigar, cigarette, and tobacco stores and stands.

Coal, wood, and ice dealers.

Drug stores.

Feed stores, farm implements, and farmers' supplies.

Florists.

Gift, art, and novelty shops (including souvenirs).

Jewelry stores.

Luggage and leather goods.

Music stores, pianos, radios.

News dealers.

Office, school, and store supply and equipment dealers.

Opticians.

Sporting goods, athletic and playground equipment.

Stationers and printers.

Seeds, bulbs, and nursery stock.

Not otherwise specified.

Second-hand stores.

Automobiles.

Tires, accessories, and parts.

Furniture.

Pawn shops.

Clothing, shoes, etc.

Other second-hand stores.

The Census Bureau recognizes half a dozen definite types of retail organization:

Single store independents.

Two-store multiples.
Three-store multiples.
Local chains, four and over.
Sectional chains.
National chains.
Other types of organization.

Which types of stores will present any given product most effectively to those groups of people who constitute the best potential customers? That question can be answered only in terms of particular goods. It is different for each item; it may even be different for different sizes or styles of a single item; it may be different for the identical item at different times. No generalized answer can be made. But before a producer tries to decide which intermediate channels of distribution to use he should select the kind of retail selling, and the types, classes and locations of retail stores which his product demands. Then he is in a position to pick the channels best calculated to reach those retail outlets.

Choice of Intermediate Channels. Picking the most effective retail outlets is usually a difficult step because the reasons for choice are little understood. But when that choice has been made the next step falls into place fairly readily. In each trade there are fairly well-defined channels. In general it may be presumed best to use them although at present changes are taking place so rapidly in many trades that it may not be at all obvious which methods of distribution will shortly prevail.

It is usually expensive as well as uncertain, to distribute any product to a selected class of retailers by some method not commonly used for their particular group. For instance if it has been decided to distribute an article classed as stationery to dry goods stores the latter would probably be more effectively reached through dry goods jobbers than through stationery jobbers.

Moreover it is probable that the jobber who is well entrenched in his territory could sell more effectively to his regular retail customers than the manufacturer could sell direct, unless the retailer is accustomed to buying direct or unless he is dissatisfied with the jobber's service. Such is the generalization but the fact in many trades is that the jobbers have encouraged or permitted manufacturers to send "missionary salesmen" to their retail customers and have fallen down in other services until the retailers have learned that they can get service direct better than from the jobber. The jobber has pushed this idea along, moreover, by carrying less and less stock and leaning more and more on his suppliers for quick deliveries so that in some trades the jobber's appearance in a sale at all may be merely an added expense and bother in a matter better handled without him. His continued existence is merely a matter of courtesy and charity (sometimes wrongfully called "loyalty").

Between these two extremes of usefulness and uselessness are found most of the jobbers. The important factors on which must be based the decision whether to use them or not are (1) just where they are on the scale and (2) in which direction they are moving. Furthermore, what is said of jobbers is also true of each of the other agencies of distribution—agents, brokers, factors, converters, commission men, traders, and so on.

List of Intermediate Channels. In general a producer may have the following choices for his primary distribution outlet:

A. With his own sales force.

1. Direct to consumers.
2. Direct to retailers.
3. Direct to wholesalers or jobbers.

B. Through a sales agent or factor who undertakes to dispose of the entire product.

C. Through brokers to wholesalers or industrial consumers.

D. Through wholesalers to retailers by the process of supplying the former with goods on consignment (or through retailers to consumers by the same method).

The four major groups represent increasing degrees of scattering the responsibility for sales as you go down the list. Other things being equal these channels would naturally become correspondingly less and less effective. Unfortunately, however, other things are seldom equal so that generalizations would be misleading. Consideration should be given to each possibility in choosing the marketing plan for any given line of products. In general the choice should be made in terms of profits. There are three factors which control profits: (1) cost, (2) volume, (3) price. That channel should be selected which will give the greatest net profit keeping the cost of selling as low as possible and both the volume and the price (that is the net sales price received by the producer) as high as possible.

Increasing the *cost of selling* may result in greater *volume* up to a certain point after which further increases in cost will no longer be effective. Decreasing the *price* likewise will often result in increase in *volume*. Increasing volume beyond its normal point, at a given *price* level, will cause *costs* to increase faster than the additional returns from the greater sales. The aim in choosing marketing channels is to discover that adjustment of the three factors which will yield the greatest net profits. Unfortunately, executives frequently miss one or another of the variables in the equation, sales managers are seldom given the four-variable view of their problem and salesmen never are permitted to consider any but the volume variable. These facts partly explain why there is so much unsound marketing in American industry today.

There are special considerations which should be taken into account with each of the choices of intermediate distribution channels:

A. *Selling by the company's own salesmen* permits control which is not attainable by any of the other methods. Under this system only can the company insure *greater* effort when sales are low and *less* effort when they come easily. All selling psychology tends in the opposite direction; efforts usually are relaxed when selling becomes harder, but all the salesmen jump into their work enthusiastically when sales come easily. This is partly human nature and partly the result of the common but unscientific system of paying salesmen either largely or wholly on commission on net sales.

Advertising and selling efforts can be coordinated when both are controlled under one executive. Sales planning or budgeting, the use of sales quotas and control over sales territories are completely available only when the management is unified.

Economies of operation are being introduced on the use of directing, routing, and supervising of salesmen and are forcing competitors to follow.

1. *Selling direct to consumers* is a difficult and expensive game for any manufacturer. The unit sales must be big enough to cover the costs of making them. If the unit margin is enough to absorb the sales effort, or if the volume is naturally so large that mass selling methods can be used and thus unit costs reduced, then some form of direct-to-consumer selling may be devised which will be successful in terms of net profits.

The three principal methods open are (1) by mail, (2) by direct canvass, (3) by company-owned retail stores. The last has been successful when the company has enough of a line to justify a retail store. The store may, of course, handle lines from other manufacturers, but the plan has seldom proved successful unless the lines of the company which owns it represent the bulk of the store's business.

Direct selling by canvasser and by mail have already been discussed. They should not be attempted unless the volume is large.

2. *Selling direct to retailers* is coming more and more into popularity as retailers are learning to buy. The chains have shown the way. Retail cooperative buying is growing faster than chain buying. Already there are more retail grocery stores associated in cooperative buying organizations than there are chain stores but their volume of sales has not yet caught up to that of the chains.

Department stores have long bought direct. Now chains of department stores are being formed for the purpose of demanding lower prices on larger-volume purchases. From a cost standpoint such lower prices are justified only if the buying is done in such a way as to decrease the cost of selling on the part of the suppliers. So far chain department stores have usually proven more costly, rather than less costly, to sell to, because each unit has had to be sold just as effectively as ever and the head organization is merely an added hazard for the task of selling.

Recently one manufacturer, figuring selling costs, found that sales to the largest department store cost more than to any of the smaller ones, because after the sale was made the goods were ordered out in small lots and more service required on each than was demanded by any of the smaller stores. Yet the big one demanded a special discount. It was decided that it did not pay to seek his business even though it did represent considerable volume.

Chains buy direct and demand greater discounts than granted to wholesalers. Whether or not they are entitled to such discounts is a matter for argument. Whether or not a manufacturer should sell to them with extra discounts should be answered first in terms of the net profits equation; if they lower the cost of selling to them and increase volume sufficiently they may justify the lower net return to the supplier; second the supplier must face the question whether or not he is taking extra risks by getting "too many eggs in one basket."

Some items, notably mayonnaise, yeast, and coffee, are being successfully marketed by wagon direct to individual stores, independents as well as chains. In some instances the wagon routes are owned and operated by the manufacturer. In others, especially in Texas and Oklahoma, wholesalers are

establishing wagon routes and developing the new form of wholesale distribution. This is too expensive a method to be used except in the distribution of large volumes of small-unit items which are to be found principally in food lines. It may prove of importance in the distribution of quick-frozen meats, fish, and fruits as the use of this process grows.

3. *Selling direct to wholesalers or factors* is the traditional standard form of distribution. It is, however, undergoing a severe test and many trades are eliminating it as an unnecessary step in distribution. The principal justification for wholesalers was formerly found in the geographical necessity of having stores of goods at each principal city for distribution to the retailers in the city and vicinity. The speeding up of transportation has greatly reduced the need for such stores, at least at points east of the Mississippi River and north of Washington, D. C. where twenty-four hour delivery is possible so that stocks at the factory are often sufficient to meet hand-to-mouth buying requirements.

Furthermore, there has been a large proportion of wholesale houses which have fattened on easy times and have degenerated into order-taking establishments. The necessity for doing real selling has driven wide-awake manufacturers to send out missionary salesmen to get orders for their wholesale distributors. Obviously there is a limit at which it becomes cheaper to do the business direct than to pay commissions to wholesalers who neither stock adequately nor sell effectively.

In spite of these conditions, which are growing, it should be recognized that the bulk of the so-called "consumer goods" still goes through wholesalers. It should also be recognized that many wholesalers have seen the trend towards direct-to-retailer selling, and the causes therefore, and are taking steps to justify their continued existence. They are improving their selling methods, and they are forming "cooperatives" and constituting themselves the buyers for "member" retailers. Such organizations are eliminating many unnecessary wastes of competitive selling and by cutting the costs of distribution are putting themselves in a position where they can market the goods cheaper than the manufacturer can sell direct to the retailers.

The existence of modern wholesalers scattered among the old-style wholesalers makes it necessary to look into conditions in each territory separately. Many manufacturers are well advised to sell by one method in some places and by another in others, watching for the new crystallization of distribution methods before committing themselves to definite policies.

B. *Contracting with a sales agent or factor* to sell the entire output of a factory, the old typical method of cotton mills, still widely used in the textile industry and some few others, is a holdover from an economic era which has passed. A century ago when the textile mills were being organized it was generally held that factory managers and sales managers were entirely different kinds of people who could not understand each other's problems and who operated better independently of each other.

Now we are alive to the necessity of coordinating the production and sales programs. Independent operation seldom works successfully. Most of the independent sales agents or factors have tended to give the factory too much to do in prosperous times and not enough in bad times. In ordinary times

moreover their tendency is to push the easily moving lines at the expense of perhaps more profitable lines for the factory. Efforts to control the situation have usually resulted in friction rather than better coordination.

Contracting with an agent to market the entire production is an easy way for the factory organization to "duck" the problems of selling and consequently many of the old style arrangements still hold on. Only in an occasional instance, however, is the plan working with sufficient satisfaction to warrant continuation.

What is true of sales agents also holds in large part for manufacturing companies having their own sales organizations, but keeping their sales executives apart from the production executives, perhaps in different cities. The incentives generally used are not calculated to secure the cooperation needed between the factory and the sales organization.

C. Selling through brokers is next of kin to having one's own salesmen on commissions based only on net sales, except that the control over the broker's salesmen is lost completely. In either case the selling effort goes primarily to the easiest selling lines which are often the lines in which there is the least profit. This tendency can be counteracted to some extent with company salesmen but is entirely out of control with brokers. There are certain staple goods, however, where such control is not essential and in such few cases the use of brokers may be adequate. There are other cases where the volume of sales are not sufficient to warrant the maintenance of salesmen on full time and in certain instances of this nature the use of brokers again may be justified.

A warning however should be made at this point. Where sales are thin and scattered so that the use of full time salesmen does not seem justified in a given territory it often proves too expensive to sell at all in such territory. In such instances it is usually desirable to consider the possibilities of more intensified selling in concentrated areas and the discontinuance of scattered sales efforts.

Only an analysis of costs, and experiments with the possibilities of volume to be attained by each method, will reveal the better choice of marketing technique.

The economies being introduced in controlled selling based on market analysis, sales quotas, salesmen's routing, and modern forms of salesmen's compensation are making the inefficiencies of the brokerage form of selling stand out sharply in contrast with the use of company sales forces.

D. Selling on consignment has always been done but the idea has lately come into more prominence as a scheme to control resale prices. Certain manufacturers who have been bothered by cut prices on their products offered by intermediate distribution agencies have experimented with this form of selling.

One of the few apparently successful instances of use of this plan is on a minor item sold in drug stores. Exclusive contracts were made with some 200 selected distributors which included an agreement on their part to report inventories of stocks on hand once a month. Later, when they were given the option of buying outright or taking goods on consignment, only eight jobbers elected to change to outright buying.

Fig. 7.—County outline map of the United States. (By permission of the National Industrial Advertisers Association.)

Fig. 9.—County outline map of the United States. (By permission of the National Industrial Advertisers Association.)

The difficulties lie in the fact that jobbers who handle goods on consignment are legally agents of the manufacturer and he becomes responsible for their acts. He has little control, however, over them. Furthermore, the jobbers' stocks are inventory of the manufacturer. There are heavy carrying costs, but again there is little control. Experience of some users of the consignment method of selling is that an increase in price will bring in large volumes of predated sales reports from the consignees, while drops in prices will bring to light unsuspected volumes of inventory in their hands. Manipulation of consignment stocks by the agents is too easy to be avoided in all cases by any known method of control.

Selling at retail on consignment is also practiced, usually accompanied with the use of "hidden demonstrators." This plan has been used quite extensively at cosmetics counters in department stores. It is in effect a form of selling direct to consumer, but is included at this point because the consignment element is of more importance than the direct selling.

It should be noted that the consignment method is usually popular with distributors because it supplies them with stocks for prompt delivery without carrying charges and without their having to assume the market risks on price fluctuations.

Industrial Markets. Any of the above kinds of channels of distribution may be used in approaching industrial markets. There is an added factor, however, which modifies, for industrial goods, many of the conclusions which might be reached for the marketing of consumer goods. This special factor is the concentration of the market. There are 3,073 counties in the United States. According to the Bureau of the Census a quarter of the total materials used by the industries of the country are used in 8 counties. One-half the total volume of purchases are in 37 counties and three-quarters in 143 counties. Of the total production of manufactured goods, 83 per cent is carried on within 345 counties (see Figs. 7, 8 and 9).

With such concentration the costs of selling can be greatly reduced. Sales effort can be directed to compact territories and the machinery of marketing correspondingly simplified.

The So-called Marketing Revolution¹

The so-called marketing revolution of the last decade is not a revolution in the sense that the characteristics of the movement and beginnings of the movement took place within that period. The changes which have taken place in the marketing structure and organization are no different in kind than changes which were taking place before the war.

The distinction between the two periods lies largely in the rate of change. In all lines of business the characteristic of the past decade has been increased rapidity rather than novelty of change. This point was emphasized in the report of the Committee on Recent Economic Changes. The development of chain stores since 1920, the development of the cash-and-carry wholesaler, and extension of the buying syndicates involve movements which were known in the prewar period, but the rate of development has been much more rapid in the past ten years than earlier. This acceleration of change is equally

¹ From TOSDAL, HARRY R., "Trends in the Manufacturer's Choice of Marketing Channels," Consumer Marketing Series, No. 2, American Management Association.

true in the marketing organization, and had had decided effect upon the calculations of manufacturers in their choice of marketing channels.

The manufacturer of today who is confronted with the problem of choosing marketing channels will find himself compelled to pay special attention to three general developments of the past decade:

The first of these is the result of a variety of factors that may be expressed by the phrase "growth in the intensity of competition among sellers." There seems to be an increased intensity of competition among sellers which has been brought about by a diversity of developments:

1. The increased capacity of plants as the result of construction of new plants, of new processes, and of improved machinery, management, and transportation. The result has been an enlargement of productive capacity at a rate which has exceeded in many lines the rate of increase in consumption capacity as limited by income. The tire industry may be cited as an example. Change in production management, new processes, and the use of new machinery have made it possible to develop output to 8,000 tires a day in a plant that a few years ago produced less than 5,000.

2. Competition has increased in intensity likewise as a result of increase in the number of industries which are competing for a share of the consumer's dollar. In other words, both intra- and inter-industrial competition appear to have increased in intensity. There are, of course, other factors which tend to make competition seem more or less intense, such as the changes in purchasing power due to rate of employment, changes in price levels, and certain types of changes in consumer demand.

The second significant feature of the so-called revolution has been the growth of large-scale buying. In studying the distribution organization, we notice the increase in the rate of development of large scale buying through several types of organizations, such as chain stores, large department stores, voluntary associations of retail merchants, buying syndicates, as well as larger-scale buying as the result of mergers and consolidations.

Large-scale buying existed and was developing before the World War, but the growth since 1920 seems at this close range to have been much more rapid, as affecting a wider range of commodities and commerce and a wider group of manufacturers. The manufacturer of a grocery product today finds himself attempting to sell to independent wholesale grocers (who may be combined in an association), to chains of wholesale grocers, to wholesale grocers with special contractual arrangements with a group of retail stores, and to a decreasing number of small independents both in the wholesale and retail field.

An examination of the field will emphasize the importance of the development. Large scale buying by retail stores becomes a concrete reality when it is reported by the Commercial Service Company that on July 1, 1930, there were 8,206 chains in various fields with an average of 25.7 units each or a total of 211,159. Only about 20 per cent of these have reported to the Federal Trade Commission, but they represent approximately 31 per cent of total outlets and an even greater percentage of total sales.

In the grocery trade the development has been relatively largest, since 1,025 chains control over 80,000 units, an average of 78.5 units per chain. It is estimated that regular chains control 35 per cent of the grocery trade. In addition to the regular chains in the grocery trade, there are also the voluntary chains of several types. According to a recent report of the Food Research Institute there are in the United States a total of 551 voluntary or cooperative chains, with 59,640 members. From the viewpoint of the manufacturer, the characteristics of large-scale buying are likely to appear

in dealings with voluntary chains whatever the form, since contracts generally limit the manufacturer's liberty to deal with member retailers. Since voluntary associations are estimated to control 25 per cent to 30 per cent, the two types of large-scale buying control a total of 60 per cent to 65 per cent of the retail food distribution. While the percentage is unusually large in this particular field, we cannot overlook the fact of increased importance of chains, mutuals, buying syndicates, and similar organizations in other trades.

The increase in concentration of buying power, is therefore, evident. The significance of such concentration for the manufacturer who is choosing marketing channels is likewise evident.

Large-scale purchasers tend to demand direct dealing with the manufacturers. As a consequence, the pressure exerted by large-scale buying is toward shortening of the process when the large-scale buying develops in the retail trade. Today the manufacturer finds himself confronted with relatively few large-scale buyers; whereas formerly he dealt with hundreds or thousands of small-scale buyers.

Policies of many of the large-scale buyers, namely, limitation in the number of products handled, purchase on specification without regard for brand, and insistence upon low prices are all influences making toward integration on the part of the manufacturer. When markets become so concentrated, the manufacturer's independence becomes as seriously threatened as did the retailer's become when full line manufacturers insisted upon control of the independent retailer's operations.

Last, but not least, of the factors which affect a manufacturer's choice of marketing channels, is the speed and certainty with which consumers now make their demands known, respected, and effective. Technical developments of communication, the progress of education, the rise in the standard of living, are a few of the factors responsible for this change—again an acceleration rather than a change in type. The fact that consumer demands are now much more effective, in other words, that the consumer takes what he wishes rather than what is offered to him, imposes upon the manufacturer the necessity for providing in some way or other for a contact which will insure that his product and his policies are in accord with that which the consumer desires.

The general developments in the marketing organization during the past decade have certainly increased the pressure toward more direct and speedy functioning of distribution systems. This basic tendency seems to be either to shorten the channels for distribution of consumer goods or to adopt compromises or agreements which will yield the same results of closer contact with the ultimate market. Marketing functions cannot be eliminated but a more direct and simple set-up for performing those functions will be the outcome.

CHAPTER VI

SETTING THE SALES QUOTA

BY C. FREDERICK HANSEN, *Director of Standards, W. T. Grant Company*

The preparation of sales quotas is described in the following pages under four main topics:

1. Purposes of sales quotas.
2. Procedure for developing sales quotas.
3. Factors considered in determining sales quotas.
4. Modification of sales quotas during the operating period.

The process of setting quotas will be outlined as far as possible in a typical or representative way, so as to indicate more than the present practices of one company or one line of business.

1. Purposes of Sales Quotas. Before going about the work of setting sales quotas, it is well to define the main purposes which they are to serve, or the uses to which they will be put. The quotas can then be made instruments for accomplishing those purposes. There are so many possible roads and lanes to follow in preparing sales quotas, that an exact statement of purpose will aid in keeping to the road and reaching the desired destination.

Some of the uses for sales quotas may be summarized as follows:

a. To designate a goal to be reached, on which all the members of the organization are agreed. This unifies their work, and stimulates them to greater effort.

b. To measure efficiency. At the end of the period, actual sales may be compared with sales quotas to show how successful each part of the sales organization has been. Such comparisons may aid in questions regarding salary increases, promotions and transfers of men, changes in rank or responsibility, and plans for supervision of sales units.

c. To provide standards of performance, which will guide the sales forces during the period of the quotas.

d. To control the amounts to be invested in capital expenditures. A certain ratio of sales to each dollar invested may be required.

e. To control expenses. Each kind of expense, or all expenses, may be kept within certain bounds expressed as percentages of proposed sales. Advertising expense, for example, may be so controlled.

f. To determine how large a sales force, or what kind and organization of sales personnel is desirable. A program of recruiting and training salesmen may be based partly on sales quotas.

g. To provide a basis for compensation. Salaries, as well as commissions and bonuses, may be determined with the use of sales quotas.

2. Procedure for Developing Sales Quotas. There are usually three stages in the process of preparing sales quotas:

a. The preliminary stage in the main office, during which the basic plan and main sales policies are formulated.

b. The developmental stage in the field, during which the selling personnel make estimates of sales for quota purposes or revise or review the estimates furnished them as tentative quota figures.

c. The final stage in the main office, during which the quota estimates as modified or suggested by the field forces are reviewed, checked, compared with other parts of the operating budget, and finally issued to the organization for use.

This description of the process indicates that sales quotas, when completed, represent a mingling of estimates and judgments derived partly from the main office and partly from the field. Usually both viewpoints are needed: the main office for its grasp of the total situation and prospects, the field for its close knowledge of customer needs, sales difficulties, and sales possibilities. The circulation of quota estimates among the field forces has the advantage, also, of increasing the sense of proprietorship by giving some voice in quota settings to those persons who must carry out the work of finally attaining the quotas.

The size of the company and its type of organization will of course affect the assigning of powers and duties regarding sales quotas to the main office and to the field forces. In the case of large companies with highly developed district offices, the entire detailed process may be delegated to those offices, and policies and total summaries only may be retained in the home office.

The type of sales campaign to be conducted also affects the quota setting procedure. For example, a certain grand total amount of sales may be decided upon, more or less arbitrarily. The attaining of this total is assigned as a task of the whole sales organization. Then the detailed process of quota setting consists of dividing and subdividing properly the total amount, so that each unit or each individual must secure his fractional share of the total sales requirements.

The typical sales quota procedure, however, involves a series of appraisals in which both the home office and the field forces participate, passing through the three stages outlined above. In a more specific way, the development of sales quotas follows the routine depicted in Fig. 1: Course of Development of Sales Quotas.

The steps in this procedure as indicated in the chart may be summarized as follows:

a. The sales manager after consultation with the general manager, prepares a general outline of sales plans and strategies for the period to be covered by the sales quotas, indicating proposed total sales by districts and by lines or commodities and showing the proposed percentage of increase in each classification.

b. His outline is discussed in conference or sent successively to the other department heads in the main office, who modify it in the light of com-

pany requirements regarding finance, expense control, production, and merchandising.

c. After the general plan is agreed upon, the sales manager's office draws up work sheets for sales quotas, arranged for convenient use by the field forces for making their estimates for sales quotas. Accompanying these

Symbols:

Origin of sales quotas

— First stage: preliminary stage in the main office, during which the basic plan and sales policies are formulated

— Second stage: the developmental stage in the field.

- - - Third stage: the final stage in the main office.

Completion of sales quotas.

After completion the final sales quotas follow the outward course shown in the second stage in being issued to the sales units.

FIG. 1.—Course of development of sales quotas.

work sheets may be some useful aids, such as last year's sales for the respective field units; company averages showing the percentage of total sales secured on each commodity or line; program of promotional drives; merchandising changes, as price changes, and other information. The design of the work sheets should be such as to facilitate the computing of totals and cross totals.

d. These forms and information are sent to the field executives who review the estimates for the total division or district and for each unit therein, and add comments or suggestions for the benefit of the individual salesmen or managers of the primary sales units.

e. Individual salesmen or managers of the primary sales units enter their sales estimates on the sheets in the light of both the data furnished them and their own local experience.

f. They forward the sheets as filled in to the field executives who review and revise them and compute the proposed sales for the whole district.

g. The field executive then forwards the sheets and summaries to the sales manager in the main office, who reviews them both in detail and in totals. He makes such changes as are advisable in the light of the totals shown for districts or for lines of commodities.

h. The proposed sales quotas are reviewed successively by the heads of departments in the main office or in conference. After final agreement is reached among them, the quotas are reviewed by the general manager, who compares them with long-time trends, last year's attainments, last year's quotas, and the tentative production schedules, budgets for expense and capital expenditures covering the same period of time as the sales quotas.

i. Individual quota records are then prepared in the main office for each sales unit and summaries are prepared for each district. The record forms used for sales quotas should be convenient for handling. Spaces should be provided for the field forces to enter actual sales opposite the quotas. The importance of the quotas can be brought out by the arrangement of the quota record.

j. Sales quotas may be issued in conjunction with other kinds of quotas covering expense budgets, merchandise stock quotas, or proposed gross profit or net profit.

3. Factors Considered in Determining Sales Quotas. All of the factors that should be taken into account in determining sales quotas may be grouped under four main heads, as pertaining fundamentally to:

Sales promotion and merchandising.

Production.

Finance and expense.

Organization and personnel.

The individual elements within each of these groups of factors are numerous. In some kinds of quota setting, not all of them need to be considered. But usually danger lies in basing sales quotas on too scanty a review of factors. If they rest on only one premise, such as the continuance of a fixed rate of gross sales increase, quotas may run afoul of certain factors which should have been foreseen, such as the amount of available working capital, expense control, balanced sales of different commodities, increased competition, training of the sales organization, and many others.

These factors are outlined in Fig. 2, grouped both according to functional classification and also according to position of the persons weighing them, whether in the main office or in the field.

Sales Promotion and Merchandising. The Desired Volume. The sales program for the period of time covered by the sales quota may emphasize

quantity (volume of business) to be secured, or *quality* (the sort of business) to be attained; or it may require a balance between quantity and quality. If the aim is for volume, care should be exercised in setting a total sales quota which is reasonable.

It has been found that quotas set at abnormally high figures easily may cause harm by arousing unfavorable attitudes on the part of the sales force. When actual achievement falls far below sales quotas, disappointment and loss of morale may follow; when quotas are exceeded, the resulting pleasure and pride in achievement strengthens morale.

<i>In the central office</i>	<i>In the sales unit</i>
1. Sales promotion and merchandising	
Desired total volume of sales	Local analysis of:
Desired quality of sales	Facilities and equipment
Allocation to territorial units	Customer attitudes
Plans for territorial coverage	Competitive conditions
Allocation to commodity lines	General business conditions
Allocation on time basis	
2. Production	
Production capacity	Service, especially deliveries
Desired production	
Time schedule for production	
Turnover of warehoused stocks	
3. Finance and expense control	
Capital requirements to attain sales quotas	Relation to expense
Relation to cash budget	
Relation to standard return on investment	
Relation to expense	
4. Organization and personnel	
Program for recruiting and training field men	Development of personnel engaged in selling by use of individual and group methods
District classification and lines of authority	
Promotions, transfers, and demotions	
Morale	

FIG. 2.—Factors considered in determining sales quotas.

An indication of good quota setting usually appears when in approximately half of the cases, the quotas are exceeded by the field units, and in the other half of the cases are not reached. Under normal conditions, this indicates that the tasks were reasonable, and a sense of fairness attaches to the quota system.

General business conditions, and the general status of the line of business engaged in, require careful appraisal at every stage of setting the sales quota. Forecasting of business trends may require extensive research.

A merchandising consideration with much bearing on sales volume is the changing or maintenance of prices. It may often be assumed that the greatest percentage increases in sales should occur where the greatest reductions in price are made; but there are many reasons why this does not always follow. The proposed volume of sales should be estimated on the basis of prices consistent with the trend in each commodity.

The Desired Quality of Business. The pursuit of volume without reference to many other considerations equally or more important for a satisfactory net profit is a crude method of operation. Sales quotas in most lines of business may be established on a basis which requires quality as well as quantity of sales.

Some of the ways in which such a balanced job can be assigned to the sales force are listed here. Not all of these, of course, are feasible in a particular business, nor should too many of them be introduced at one time into the sales quotas.

Quality requirements appearing in the sales quotas might consist of:

a. A definite proportion of total sales to be secured on high-profit commodities; or a specified *average percentage of profit* on sales for the period may be required.

b. A certain amount, or proportion, of sales to be derived from *new accounts*, or new customers.

c. A standard amount, or proportion, of total sales to come from *old accounts*, representing persistency of regular customers.

d. A proper *assortment of lines* or items to be shown in total sales; each item assigned a standard percentage to total.

e. A specified *average sales transaction*, indicating the size of individual sales.

f. The *number of items included per sale*, showing the thoroughness of the canvass made of each customer.

g. A standard "*service*" to be rendered in connection with each sale or for each customer.

h. A *quota expense percentage* to accompany the sales quota. (A discussion of expenses in relation to sales quotas appears in another section below.)

If the quality of the sales to be attained requires more emphasis than is given by including quality standards in the sales quotas, a powerful incentive toward that end may be introduced by basing the compensation system partly on quality standards. Commissions may be paid on a sliding scale based on quality of business or on net profits; bonuses may be awarded for attaining these features of the sales quotas; deductions may be made from scheduled pay if these standards are not attained.

Assigning Sales Quotas to Territorial Units. Study of territorial sales possibilities is a subject sufficiently complex to justify comprehensive research on the part of any selling organization. The ideal analysis of territories would reveal the potential sales for a given period of time so accurately that actual sales in each territory for that period, taken as a percentage of potential sales, would furnish an index of efficiency of selling in each territory.

Potential sales of an area are controlled by two considerations: (a) desire or demand for the commodity on the part of potential customers, and (b)

purchasing power to buy it. The first of these involves consumer psychology, with specific reference to the commodity. The second involves consumer economic strength. Both of these will fluctuate with time.

There are considerable data available showing the relative economic strength of the parts of the United States. Government sources include such publications as the Census of Population, of Manufactures, and of Agriculture; the new Census of Distribution; Federal Reserve bulletins; business surveys prepared by the Department of Commerce, and others.

Trade associations publish statistics reflecting territorial output of products, consumption, and sales. Newspapers, magazines, advertising agencies, and marketing concerns contribute many kinds of economic data. Sources of market information are listed in a publication of the Department of Commerce, called "Market Research Agencies." Some of the available series of economic facts provide them not only by cities and states, but by counties.

Territorial data therefore are at hand concerning population variously analyzed, for agriculture, mining, manufacturing output, retail outlets, income tax returns, cost of living, telephones, automobiles, wired houses, magazine circulation, life insurance, bank deposits, and many other measures of economic life.

The country changes and grows rapidly, so that the published statistics after a few years become obsolete. For many of these series of data, percentages of increase or decrease from time to time may be figured. Sometimes the rate of growth or decline in these measures of economic life are of great significance, especially for a business, which, after entering a community, requires several years to establish itself on a profitable basis.

Parallel Data within the Company. For the territories which the company has in the past covered with its selling organization, there are actual sales records available, usually in considerable detail. The relative value of sales facts from within the company, as against economic statistics from outside sources, for distributing sales quotas to territories, should be determined in the light of several considerations.

Company sales records are relatively more valuable for market analysis than outside data if the company sells staple commodities, has marketed them for many years, has cultivated the sales territories consistently for years, has adhered to certain sales promotion methods for years, and in short, has found its place in the field.

Outside data from the market are relatively more valuable if the foregoing considerations do not hold; if the company sells style or novelty or specialty items, is invading new fields, using new sales promotion methods, and seeks a new status.

Selecting Pertinent Factors. The problem in territorial analysis is one of determining which economic facts and which local psychological factors will provide the best measure of potential sales of a commodity. One or more of several methods may be used for sifting out those factors which are most pertinent. Four of these may be stated and evaluated.

First, the method followed may be to use those factors which furnish *broad, fundamental information* about each territory, such as population or a large part of the population (race, sex, literacy, etc.), value added by manu-

facturing, or facts relative to wealth and income. Reliance upon a few general facts for judging the value of territories, while sometimes crude, has the advantage of simplicity and may furnish as exact a measure as is justified by the practical uses. Such data are available for small units of territory. Another advantage is that economic data which may be more specific for the products to be sold, tend to correlate highly with population and other broad data.

The 1930 Census of Population and the new Census of Distribution provide fresh general information about territorial purchasing power.

Second, the factors to be used may be selected on the basis of specific *customer analysis*, logically deducing from the prevailing type of customer those economic factors which describe him. The typical customer may be described in terms of occupational groups, income groups, educational groups, etc., and statistics selected which measure the number and purchasing power of those groups. This method of selecting pertinent factors has much value. Its weakness lies in its tendency toward arbitrary assumptions, based on generalizing from premises which may not give a comprehensive description of customers. This method also is likely to ignore the variations existing in the prevailing types of customer, from place to place.

Third, those economic data may be utilized for territorial analysis which indicate the *total sales and business of the trade* to which the company belongs. In many cases, trade associations compile sales facts revealing the relative value of territories for the trade.

A useful principle, when such data are available, is to find what percentage of all companies' combined business is done by the one company, in each territory; then to project the trend of the combined business and compute the quotas as the same percentage of the future total as actual sales have been in the past. If the company's percentage of the total business has been increasing or decreasing in any section, this trend may be taken into account in determining the company's share of future business.

If, for example, the company's Kansas agency has in the past year secured 8 per cent of the total business of all companies competing for the Kansas business, it is generally reasonable to set as the sales quota for this year, at least 8 per cent of the anticipated volume of all companies in that territory.

This basis for quota setting is useful more as a supplementary basis than as the fundamental guide. Usually such trade statistics are not available until much of the year has elapsed, and by the following year new changes in the trade may appear. The dropping out or addition of competitors may change the percentage of total business for the company. This basis of planning sales has the further disadvantage of fixing attention more on what all the competitors are doing than on what are the inherent merits of each territory and all territories.

Fourth, the statistical method known as *correlation may be employed* to discover the tendency of sales to run parallel with any economic series. If a perfect correlation is found to exist—if the highest territory in sales is by the same relative amount highest in the economic factor, and the second highest in sales is second highest in the economic factor, etc., down to the lowest in sales corresponding with the lowest in the economic factor—the

correlation is $+1$. If no relationship is found to exist, the correlation is 0. If the highest in sales is the lowest in the economic factor, and so on for every territory, the correlation is -1 . Actual correlation coefficients may be at any point between the extremes. By means of multiple and partial correlation, the various factors found to correlate with sales may be assigned weights, so that their combined index will have the highest correspondence with sales.

This method has in the past ten years been tried out by market statisticians for different types of companies—life insurance, chain stores, meat packing, and others. It would probably prove useful in companies, the sales data of which lend themselves to this method.

Some of its weaknesses may be illustrated with the experience of a life insurance company which in 1920 used the correlation method for determining sales quotas of all their agencies for the following year. The relationships discovered existed for 1918 and 1919, but abrupt changes in economic trends in 1920 and 1921 overturned them.

Relationships between sales and other data measured in terms of correlation coefficients may be applied to the future by assuming that these external forces will continue to maintain their positions relative to the company's sales and that the future sales efforts of the company will be exerted in the same way. As a matter of fact, both the external and internal factors are like streams flowing in somewhat different directions, with different volumes and rates of flow, sometimes abruptly changing, so that the exact relationships discovered may not continue to exist.

There are so many uncontrolled variables when correlations of business data are figured, that the coefficients usually have been found to be low, and the "probable error" is high. This has been found the case in chain store data. When the territorial units used in the correlations are states or territories of any considerable area, the number of cases tabulated is so small that it indicates a high probable error.

The assumptions underlying the use of correlation methods for sales quotas under many conditions may be questioned. As a practical tool, this statistical method would measure sales relationships in terms of millimeters while practical working forces playing upon the situation would call for measurements in meters. Correlation methods may be useful for research in sales problems rather than for current quota operations.

Promotional Factors Locally Considered. Economic statistics and past sales records may furnish the skeleton for sales quotas, but if they are ever to take on the forms of life they must be filled in with the flesh and blood of local conditions locally appreciated. Some of these elements of considerable importance are qualitative, and cannot be statistically expressed. Some of them are psychological and exist in the habit structures of people in the community.

Other local considerations for many lines of business, have to do with the location of the sales unit on the street or in the city, and the building and equipment to be used for sales or sales offices. The amount of space available for selling purposes, its shape, use of basements or upper floors, positions of doors and stairways, amount and character of window-display space, and many other physical elements affecting potential sales may vary

widely from one sales unit to another. The effect of these elements on sales may best be determined by those who work daily with them. The greater the company's standardization of plant and equipment for sales offices, the less consideration will of course be given to these elements. In some lines of business such as retail stores, the physical environment is a very important factor. It plays upon attitudes and habits of both the selling employee and the customer.

Sales Surveys for New Territories. When the question of entering new territory or opening new sales units arises, sales estimates for those places are of great importance, because they may be the basis for a considerable investment by the company. Companies which are continually opening new units, as chain stores, have a thoroughly worked out technique for judging sales potentialities of new locations, which may be referred to here in rough outline.

Before visiting the location, facts are assembled regarding the community, such as trading area population, annual rate of increase of population, industrial payroll, number employed (men and women), average wage, chief industries, etc. On each point, a comparable old sales unit is found and sales by these old units are noted. In some cases, averages based on the company's old units may be applied to new communities.

The survey made locally includes counts of traffic at various points; analysis of traffic according to sex, age, occupation, class, race, etc., counts of salespeople in competing companies' sales units; counts of customers in those units; estimates of space devoted by competitors to various lines of merchandise; local buying habits; trends in local business conditions. Many of the data secured are compared with company averages for units in comparable territories.

Plans for Territorial Coverage. Many companies tend to open sales units in every state or in every part of the country that they possibly can cover. This expresses the desire for "national distribution." But when the costs of doing business are allocated on a territorial basis, it is often found that business secured in the more widely scattered or sparsely peopled sections of the company's territory is secured at exorbitant costs. There may follow a policy of selective selling, that is, concentrating the sales campaign in those territories which have the greatest number of prospects or the best prospects.

In setting sales quotas for commodities or services which have wide public consumption, the concentration of population in the United States in certain centers suggests concentration in territories to be covered. In the case of products which are sold to industries, for use in industry rather than by the consuming public, the concentration of the market is even more pronounced.

Of the 3,073 counties in the United States, there are 8 counties which consume one-fourth of the total products sold to industries. One-half of such industrial products are sold in 37 counties; and three-fourths of the total industrial products are sold in 143 counties. Such data easily lead to the conclusion that sales efforts should be concentrated in those areas. However, if many companies competing for sales of an industrial product pursue the same policy of territorial concentration, such factors as intense competitive bidding will enter into the question.

Analysis of sales accounts in relation to expense sometimes shows that accounts amounting to less than a certain minimum are secured at a loss. A lower limit may then be set for accepting business. However, it must be recognized that many large accounts have originated in small accounts and that the discarding of these may cut off a source of future large accounts.

Sales Quotas by Commodity Lines. The grouping of sales quotas according to territories of the sales organization tends to emphasize the *regional* aspects and to minimize the *commodity* aspects of sales quotas. From the merchandising standpoint, commodity sales quotas cutting across territorial lines and showing the goal to be reached by each commodity or line for the entire number of sales units, are very important.

The work sheets for estimating sales quotas should furnish sales data by commodity lines to serve as guides in setting down the proposed sales by lines for the sales unit. Commodity sales estimates should be totaled by districts and for the total company, and should be compared with the previous year's actual sales and quotas similarly segregated by commodity.

The trend of sales of each commodity month by month and year by year gives many clues to weaknesses in merchandising which should be recognized when sales are to be planned. The trend of each commodity's sales may be shown as a percentage to total sales of all commodities; and each of these percentages may be applied to the total sales quota to estimate the commodity sales quotas.

The sales trends of different commodities sold by the company are often very divergent, and these differences deserve consideration in quota setting. Some commodities are following an upward secular trend in sales, others stationary or downward. Some are influenced more radically than others by the cyclical forces of inflation or depression. The price trends vary among them. Style elements affect some more than others. Questions of sizes, colors, styles or patterns affect sales of some of them and others not at all. The seasonal ebb and flow of sales for one commodity will differ from those of another. Customer prejudices or likes will be directed at individual commodities, and such customer reactions toward a commodity will vary with the territory.

Sales quotas arranged by commodity lines make it possible during the period to:

- a. Exert sales pressure behind certain commodities in the total range of field units or in certain regions.
- b. Maintain sales balance between high-profit and low-profit lines so that total gross profit will be controlled.
- c. Set standards of sales by commodities; against which each sales unit can analyze the strength and weakness of its sales presentation.

Time Divisions of Sales Quotas. Under sales promotion and merchandising may be considered the time units for which the sales quotas will be subdivided—whether quarters, months, weeks, or days. The time element, of course, is involved for all factors; but since it has much importance for the sales promotion and merchandising program, it may be referred to at this point.

Sales quotas should usually be set for that total period of time which is a natural unit in operation—for example, a season—and also subdivided among the units of time most significant for sales stimulation, or for the manipulation of stocks or the demands of the customer. Monthly quotas are frequently the smallest units of time considered; but cumulative period sales quotas are also computed for the end of each month. In dividing the total period's sales volume among time units it is advisable to take into account especially:

- a. The natural seasonal fluctuations in volume.
- b. The merchandising or promotional ideas to be featured at the various times.

The seasonal fluctuations of sales may be computed either from the company's past records or from trade statistics representing all companies. The latter may be more desirable for use in quota setting because the company's past method of merchandising (or promoting sales) during a given month or other unit of time may be weaker than its method for another month; the combined figure for many companies selling the same commodities may give a more reliable seasonal index than the individual company's records.

The Gregorian calendar shows its disadvantages clearly when sales quotas are subdivided to meet its arbitrary divisions into months. A logical calendar, such as the thirteen-month calendar used by many companies, has many advantages for quota setting.

The remaining factors to be considered in setting sales quotas have been grouped under production, finance and expense, and organization and personnel. These are sometimes taken into account only for reviewing and checking the sales quotas before final approval of them. A sounder viewpoint, in many cases, is to employ these factors during all stages in developing sales quotas. Sometimes one of these will be of paramount importance, and will indicate the amount of needed sales.

Production Factors. Marketing companies frequently have no investment in factories or production agencies. For such companies, warehousing and delivery service from manufacturing sources of supply are the chief production factors considered. The sales quotas assigned to different commodities or lines should be checked against these two elements on the production side.

For companies engaged in production as well as distribution, there are at least four important considerations linking sales quotas with production: production capacity, desired volume of production, time schedules for production preceding and during the quota period, and the turnover rate of warehoused stocks if quota sales are attained.

Some companies enjoy the advantage of being able to utilize factory or shop or machine for more than one commodity, at will. Sometimes plant capacity may be changed without much variation in overhead, to fit wide variations in sales. In many cases these advantages are not enjoyed, and the management must reconcile conflicting ideas regarding the advisable sales quotas.

If the capital investment in plant and equipment is rigidly set, it may be necessary to modify the plans for sales and create additional sales plans so as to employ properly the plant facilities and to insure the proper gross income necessary for expense requirements.

The time schedules for production should be correlated with the time distribution of sales quotas. Turnover of warehoused stocks should meet standards which in most cases will be set by the comptroller. Each of these production factors should be considered in setting the sales quotas for individual commodities or lines.

Financial and Expense Factors. The financial and expense factors involved in setting sales quotas are especially:

- a. The amount of capital to be invested in order to attain quota sales.
- b. The effect of quota sales on the cash budget of the company.
- c. The control of investment to secure adequate return on invested capital, in relation to the sales program.
- d. The control of expenses, usually by setting expense budgets which will be concurrent with sales quotas.

The relation of sales attainments to capital requirements and cash budgets during the operating period is so direct and important that in many companies "financial quotas" are set on the basis of sales quotas estimated independently of the sales quotas used in the field. Such duplicate sales estimates are especially used when the regular sales quotas are set somewhat high for stimulation purposes. The financial quotas for sales are conservative so as to introduce a margin of safety in financial operations.

When these separate sales estimates are found advisable, they are usually limited in circulation to the financial heads and general executives of the company. If generally distributed, these estimates might cause confusion or might result in weakening the effectiveness of sales quotas used in the field.

Sales quotas for certain commodities or lines may involve individual financial estimates. This may be illustrated with the case of a manufacturer planning to introduce an entirely new product to his customers or an old product to a new group of customers. Cost methods may be used to determine the amount of money that will be expended and lost on each dozen of the new product sold during the introductory period. The total sales quota for the product then might be based on the total amount of capital which the company can afford to spend in a given period for the purpose of introducing the new item. If the sales promotion department finds that a certain number of thousand dozens should be sold in a given period properly to introduce the item, some agreement must be reached with the financial department for providing the capital required.

Control of Investment in Relation to Sales. The relation of sales to the invested capital may vary in so many complex ways that it is not feasible here to analyze these relationships. Under typical conditions, there should be consistent effort to secure higher turnover of each and all of the forms of company investment, in sales. Turnover should be indicated for merchandise, buildings, fixtures, equipment and other assets. The profit margin on sales and the turnover of investment in sales should be so tied together that a satisfactory return on capital will be secured.

If sales are not budgeted in proportion to existing investment or if capital expenditures are not properly controlled, the turnover of total investment is low. Assuming that two companies are equal in other things, the company

with the higher turnover of its total investment into sales will be in a position to offer better values to customers and yet secure a satisfactory return on the investment than a company with a low turnover of invested capital in sales, because in the former company a low margin of net profit on sales is compensated for by turning over the invested capital more frequently.

Expenses in Relation to Sales. Sales quotas often are set by promotional executives and field men whose temperament inclines them toward free expenditure of money. The desire of executives for a huge volume may obscure the intimate relationship which generally exists between sales quotas and expenses. It, therefore, is important that the comptroller and other executives, versed in expense studies, scrutinize the proposed sales quotas.

In many companies, operating expenses in the field are budgeted on the basis of proposed sales volume, possibly as percentages to sales. If sales quotas are set high, they automatically inflate the expense budgets. When actual sales fall below the quotas, expenses mount unreasonably high. If sales quotas are to be used in connection with setting expense standards, accuracy in sales quotas is very important.

In many cases the solution of this difficulty lies in setting expense standards in dollars on the basis of other considerations rather than as percentages of sales. Then optimistic sales quotas or temporary spurts in sales volume due to seasonal or other conditions will not throw expenses out of line.

The advertising budget usually is closely tied up with sales quotas. The pay-roll budget may be based partly on volume and partly on other operating results. Some companies have for their field forces a compensation plan involving sales quotas in such a way that the rate of commission may vary with the expenses incurred in getting those sales or may vary with the profit made on sales.

The study of sales quotas from the expense angle may result in establishing profit quotas to accompany sales quotas. Analyzing past records of the cost of selling by lines or units may lead to such steps as the adoption of lower limits for the size of an order, below which the customer pays delivery charges or forfeits certain services.

Organization and Personnel Factors. In this group of factors bearing on sales quotas may be considered especially four:

- a. The program for recruiting and training salesmen or unit managers.
- b. Reorganization of the field forces on the basis of new territorial groupings or new lines of authority.
- c. Personnel changes—promotions, demotions, and transfers.
- d. Morale of the sales force.

The subtotals and totals of sales quotas should be so computed as to agree with the grouping of individuals in the organization. Responsibility for attaining sales quotas may then be fixed upon individuals in accordance with their positions.

The program for recruiting and training men for field work is involved in the schedule of sales quotas. Usually there exist reasonable limits for sales to be required of one salesman or a sales group, and the need for men can be gauged by the desired volume of sales. A training program may be mapped out to go hand in hand with the sales program. This work may largely be

delegated to the field unit managers or district executives in conjunction with the personnel department.

4. Modification of Sales Quotas during the Period. For each time unit, whether week, month, or quarter, for which a sales quota has been set, actual sales should be compared with quotas as promptly as possible thereafter. Reports should be sent or given to each person responsible for setting or attaining a sales quota, indicating how closely actual performance has corresponded with quota sales.

Operations may show wide differences between the sales quotas and actual sales, covering a considerable length of time. When such differences exist throughout the field the bases on which the quotas were set should be critically examined. If the differences point to very complex causes, it may be found advisable to shorten or lengthen the total period over which the sales quota is to be set. Merchandising companies usually set sales quotas semi-annually to coincide with the spring and fall seasons, with monthly (and sometimes weekly) subdivisions of the total period quotas.

If the sales quota carries with it a proportionate investment in merchandise, equipment or various expenditures, it may be advisable to adjust the sales quotas from time to time during the period of operation. If this is not done, a wide discrepancy between quota sales and actual sales may during the period progressively throw the purchases or expenditures out of line with actual business.

Some of the methods in use for adjusting sales quotas during a period, so that thereafter they will conform more closely to the actual trend of sales, are as follows:

a. At the end of each month, compute the percentage by which actual sales vary from the sales quota, and adjust the next month's quota upward or downward by that percentage. A weakness in this method is that it may cause unnecessary changes in quotas by projecting temporary influences into the future. It assumes that the latest actual performance during a limited time is worthy of serving as a revised standard for future performance. The company may seem to be "backing down" on its original sales objective, and this impression weakens the standing of the quotas.

b. Another method is to allow the local sales executive on the first of each month to revise his quota for the coming month in accordance with his own judgment, based on recent operations. A difficulty with this method is that it offers too much elasticity in the field for departing from original plans for sales.

The procedure to be employed in setting and following up sales quotas may seem, after this description, to be very complicated. But if the responsible executives will attack the problem step by step they will find that the procedure is fundamentally simple and provides a clear-cut aid to management.

CHAPTER VII

THE SALES FORCE

SELECTING SALESMEN

By JOHN A. STEVENSON, *Vice President, The Penn Mutual Life Insurance Company*

Where can I get the best salesmen? What qualifications should they have? What is the best method of judging those who will make good? These are the questions which confront every manager who is building or expanding his sales force but satisfactory answers to these questions are not easy to find in the sales literature available today.

"For prompt action," writes one successful sales manager, "we find the newspapers our best means of getting in touch with good salesmen," while the next article we pick up remarks that "the poorest method of securing new agents is through advertising." One company's experience tends to show that "college graduates must have been out of school long enough to have acquired some practical experience, and the maturity necessary to command the respect of customers and prospects" while the slogan of another large sales organization is "Hire 'em green and train 'em yourself." We study through the elaborate tests which one company uses in trying to select successful salesmen only to find that another company finds no correlation between the facts brought out in these tests and actual sales ability.

No Specific Rules of Procedure. A survey of the processes and methods of selection used by successful sales organizations, therefore, inevitably leads to these conclusions:

1. There is no "best" source of prospective salesmen.
2. We have not discovered the particular qualities or combination of qualities which will guarantee sales success.
3. No scientific standard has been discovered which satisfactorily measures sales ability.

While no specific outline of procedure may be handed to the novice in sales management as the formula for building his branch of the business on a profitable basis, it does not follow that hit-or-miss methods can be depended on to establish a successful sales organization. Naturally, if enough salesmen are hired, by the law of average, a certain proportion will be able to sell. But under present business conditions, the sales manager, who depends on the law of average to give him the good producers he needs, must face the fact that the expense of turnover among new salesmen will run into rather big figures.

In the selection of salesmen, certain practices have been found to be profitable by certain sales managers who have built up successful sales organizations. These practices may not be profitable at all in other types of organizations or under other conditions, just as the general sales plan of one company may not be feasible for the marketing of a different type of product. While, therefore, we cannot draw up a set of rules to govern the selection process in the sales organization, there are certain fundamental principles on which proper selection is based, just as there are certain fundamental principles on which successful selling is based, even though actual methods of procedure may vary widely. Moreover, the sales manager who prefers to play his own "hunches" in the matter of selection—the prototype of the "born salesman" of yesteryear—is being fast superseded by the sales manager whose agency building is based on a knowledge of the practices which have been found to be satisfactory in selecting salesmen for a particular type of work.

Recruiting New Men. When a new salesman comes into a life insurance office, he is given some sales methods which experienced life insurance salesmen have found effective and then is told to experiment with various practices until he finds those which are most effective in his own case. This is about the procedure which the sales manager himself must follow in recruiting salesmen.

A survey made by one company showed for example that new salesmen were recruited from the following sources:

	Per Cent
Newspaper advertising.....	28
Personal contact of district manager.....	26
Salesmen already in the business.....	15
Supervisor.....	10
Dealers.....	10
Employees.....	7
Division office.....	3
Customers.....	1

One of these sources may be more profitable than another under certain conditions or in a certain territory but, at least, if obtaining salesmen presents anything of a problem, the sales manager in that particular business is scarcely doing a first-class job if he fails to experiment until he determines the possibilities of these various sources.

It goes without saying that the success of any method of obtaining salesmen depends on how that method is used. One advertisement may bring in salesmen and another may not, just because one advertisement is good and the other is poor. This was rather strikingly brought out by the fact that two agencies in a large company used exactly the same letter in circularizing professional men in their territories. One manager reported excellent results; the other no results. The only difference was that in one case the letters were carefully typed on high-grade paper and personally signed; in the other, they were multigraphed and a rubber-stamp signature used.

The Selection Process. Even if every chair outside the sales manager's office is occupied with prospective salesmen, the sales manager's job is by no means completed. He must at least try to select those who will make good.

So difficult is the problem of forecasting possible success among salesmen, that most sales managers consider that they have actually taken on a new producer only after he has passed the training and probationary period and has demonstrated his ability to sell.

No scientific method of selecting salesmen has thus far been developed which is worth the time it takes to read it. In most cases, the sales executive must rely on his own judgment, but there are certain definite helps on which he can depend for assistance in sizing up an applicant.

The personal history blank, in my opinion, serves much the same purpose as the company's financial statement when one is considering the purchase of stock. It gives certain information at a glance which it would be difficult to dig out for oneself. Frequent changes of employment or long gaps between the dates of positions held usually require explanation. But the personal history does not always tell the whole story and its chief value lies in the fact that it can be used to supplement the personal interview rather than as a substitute for the personal interview.

The same statement holds true in regard to personal references and reports from commercial agencies. A man quite naturally uses as references people who, he thinks, will write a favorable opinion of him and, in writing a reference of this kind, people have a tendency to whitewash the facts. On the other hand, when commercial agencies are employed to make reports, they are expected to show any unfavorable aspects in a man's life which might make it undesirable to employ him, and, therefore their reports often look pretty black. Information may be gotten from both personal references and commercial reports but they should be considered in their true light; that is, as supplementary records rather than as a final decree.

In the last analysis, the selection of salesmen is largely a matter of personal opinion. A good many organizations have several men give their judgment on a new man before they finally accept his application, but this practice represents merely the use of composite opinion in the selection of salesmen on the theory that "two heads are better than one."

Qualifications for Success. Needless to say, qualities like integrity, industry, ambition, perseverance, loyalty contribute toward success in the sales field as they would contribute toward success in any line of work. Questions such as the correlation between college education and sales success, or the value of previous experience are disputed, and, if research can help us solve the problem, it will probably have to provide a series of answers for different types of sales organizations.

Research has helped in various lines of work to give us a picture of the type of salesman who is most likely to succeed. The investigations of various life insurance companies agree, for instance, in showing that men between twenty-five and forty-five are more likely to succeed in life insurance selling than men who are under or over these ages. Similar investigations corroborate our common-sense ideas as to the correlation between physical characteristics and sales success; that is, they show more sales, on the average, made by a group of tall men than by men under average height; more sales, taking the group as whole, by men of average weight than men who are under or over the average. Other things being equal, then, the prospective life

insurance salesman who is neither very much overweight nor underweight is more likely to make a success, just as the prospective policyholder who is neither very much overweight nor underweight is more likely to live out his life expectancy. But just as the man who is the most perfect physical risk may be the first to die, the apparently perfect sales risk may be the flattest failure so that these standards are by no means an infallible guide in the individual case.

Naturally, considerable effort is required to find out whether, on the average, best results in a particular business are produced by experienced or inexperienced men, by men with a high-school education, or men with a college degree, by married or unmarried men, and to get similar information in regard to other factors of this kind which might enter into the question of sales success. However, a careful survey to determine the answers to these questions is decidedly worth while.

Interviewing. If the sales manager wants to build an agency force of men who are likely to make a success, he must accept the fact that the men he wants are not the lame ducks of other occupations, but men with opportunities to select other positions. A man of this type is going to weigh the opportunities presented by the work, but his decision will often depend on the interview, just as a prospect's decision on an order will often depend on the sales talk.

Like most interviewers, I usually begin by asking a man to tell me a little something about himself. The facts that he tells me I can usually get from the blank showing his personal history, but I get an inkling of his character from his choice of facts.

Then I go on to say: "Mr. Blank, of course you realize that this is a very important step you are going to take so we are going to take plenty of time to arrive at a sensible decision. Now I know you will understand my remark when I say that whether you decide on a connection with us is more or less incidental as far as the company as a whole is concerned—but it is by no means incidental as far as you are concerned. I want you, therefore, to weigh the matter carefully. If you do decide to come with us, all well and good, we'll do our best to help you succeed. On the other hand, if you don't, and I can help you decide on the type of work you would like to do, I will feel that I have made a friend for the company.

"When you are deciding on the kind of work you are going to undertake, there are certain questions to be answered just as there are certain questions to be answered when you are selecting an investment. Suppose you write down some that I think are very important (give him a piece of paper and a pencil) and then we can talk them over together.

1. Does the work really stand for something?
2. Is the field large enough to give me a real opportunity?
3. Is the future reasonably certain?
4. Will I enjoy doing the work?
5. Will I receive adequate compensation for the work?
6. Will I be trained for the work in the right way?
7. Is the company progressive, reliable, and sound?
8. Am I qualified to do the work?

"We have prepared a book which will give you the answers to the first seven of these questions but you will have to answer the eighth for yourself."

I then proceed to show him a book containing charts, tables, pictures, etc., which answer these questions. The book itself is an influential factor in creating an impression concerning the work and should, therefore, be attractive and handsomely printed if it is to create the right attitude toward the work which the man is considering.

While, naturally, every manager wants to present the work in a favorable light to men who, he thinks, will make good, he is making a mistake if he glosses over the difficulties inherent in the job. It is much better for a salesman to decide whether he likes the job before he takes it up than afterwards. Moreover, if he does take it up, and runs into difficulties about which he has been warned he is far less likely to be discouraged.

While no two interviews are exactly alike, I use a more or less standardized plan for this reason: it presents the clearest picture which I am able to draw of the work of life underwriting. If I do not follow a definite interview plan, I wonder after the interview is over whether I have painted the picture too lightly or too darkly. In other words, I feel that an interview plan to which I have given considerable thought enables me to meet my responsibility to prospective salesmen better than a conversation which may take any course.

Care in Selection. H. G. Kenagy stated not long ago that all the Life Insurance Sales Research Bureau knows about picking new agents can be summed up in two words: Be careful. That is all that any sales organization knows but, at least, we have come far enough along the road to realize that we can seldom pick up good salesmen "ready made" and, since the making process requires a good deal of time and effort, it will pay to exercise all the care possible in selecting our material.

BUILDING A SALES TRAINING PROGRAM

By W. W. CHARTERS, *Director Bureau of Educational Research, Ohio State University*

The fundamental principle of salesman training is that it should be based upon an analysis of the particular type of job that has to be performed. Every sales course is custom made; it is not ready-made. Every organization requires a specific course that fits it, and will not, without alteration, fit any other organization. The reason for this is that from this functional point of view the salesman in each company has to perform a set of duties different from those of any other company.

Job Analysis the First Step. We are all agreed, of course, that job analysis is necessary. But, while the principle is easy to accept and easy to understand, the methods of job analysis are more difficult. Yet sales research has been able with considerable concreteness to show how the analysis is carried on. What does job analysis mean? How shall we proceed to develop this analysis? What do we hope to get when we are through? This is a clear statement of the first task that confronts anyone who is trying to build up a training program.

Duty Analysis. There are two methods that have been used. The first method is to ask the questions: What do salesmen have to do? What are all the tasks that they have to perform? This has been worked out in a number of fields. For instance, in order to discover what the course of training for secretaries should be, a careful analysis of the tasks which secretaries perform was made. To do this two interviewers were employed for four months to interview 125 secretaries in two large cities. A list of 871 duties was compiled although not all of them are performed by each secretary. After this list had been secured it was checked by 715 carefully selected secretaries to see which of these duties they performed individually. From this a frequency list was made up showing that item 1 was performed 683 times, while item 871 was performed by only one secretary. When this was done, the basis for building up a course had been secured, because all that we have to do in a training program is to teach the secretaries how to perform each of these duties.

This straightforward analysis of duties took the time of two employees for four months but, before the study was completed we spent, in addition, the time of one person for a full year—this all at a total cost of \$4,500, not counting overhead.

Difficulty Analysis. The first method of making a job analysis is, then, to compile a list of all the duties. The second method, which applies more closely to salesmanship than the method just described, is that which is called a difficulty analysis. In other words, these questions are asked: What difficulties are the salesmen up against? Why do they not do better selling? Why are they not more efficient? In getting the answers to these questions the interview is used. Interviewers visit and observe people at work; they interview presidents, sales managers, branch managers, and the more experienced salespeople to find what difficulties they have seen learners meet, with the result that eventually a list of 50, 100, or 500 difficulties, as the case may be, is secured.

The difficulty analysis is usually a better method than the duty analysis for salesmanship training for two reasons: In the first place, salesmanship is so complicated that it is hard to state all the duties; and in the second place, it is much easier to state difficulties than to recall duties, for when certain duties are performed daily and become habitual, they are forgotten. The salesmen do not know that they perform them, but, on the other hand, they are much more conscious of their difficulties, and can recall them with considerable clearness.

In both a duty analysis and a difficulty analysis it is necessary to use the interview. Sometimes an observer is sent to watch salesmen at work as well as to ask them questions. For instance, in making an analysis of the difficulties of department store salesmanship, very little could be secured by questions. The salespeople and the managers were conscious only of the most general difficulties, but an observer at the end of six weeks, having spent two hours a day in watching salespeople, secured a list of 67. In the secretarial study just referred to, two interviewers spent four months interviewing secretaries. In making a duty analysis of homemakers one worker spent two years working up the returns after they were brought in. Ordinarily in mak-

ing a difficulty analysis, such as for salesmanship training, the list can be secured in six weeks.

Some salespeople have difficulties in personality. They have also certain routine difficulties: they do not fill out order blanks properly. They sometimes lack a knowledge of the product. There are additional difficulties connected with selling technique—the proper way to open a sale, getting information about the jobs that are coming, etc. Salesmen are confronted, they feel, very definitely with the problem of educating the merchants in the trade to become better salesmen.

It becomes the business of the training department to find the difficulties in all of these different fields, and to provide the salesmen with the information and instruction necessary to enable them to increase their effectiveness. So the department endeavors to secure a list of the different classes of difficulties, all of which need to be considered in any concerted attempt to build a training course for salespeople upon a solid foundation.

Collection of Best Methods of Handling Difficulties. When the first principle has been laid down, the second naturally emerges; that is to say, after we know what the duties and difficulties are, it is necessary to collect the best methods of handling these difficulties. The difficulties which have been worked out become the chapter headings of a manual or the topics of instruction in the early training course. The manual or the total course of instruction, if it is not put in a manual, consists of the difficulties as topics or chapters and the methods of handling these difficulties become the body of the chapters. It becomes easy to build a course of study by listing the topics and following out the second principle.

Where to Get the Material. In collecting the methods of handling the difficulties research again enters to furnish the technique. Where and how can the information be secured? The first source is the literature of the subject. When one begins to build up a course of study on the analysis basis, however, the amount of material which can be secured in printed form is extremely meagre. When a man puts his ideas into print, he expresses them in language that is much too general for this purpose. It is not specific.

A much better source from which to collect specific methods of handling difficulties is the group of expert salespeople within the organization itself. An illustration will make this clear. After the 67 difficulties of department store salespeople had been collected, 300 of the best salespeople were interviewed. They were asked how they kept their tempers with disagreeable customers, how they showed courtesy, how they displayed goods, how they closed a sale, how they dealt with mother and daughter when they were shopping together, or two friends, or husband and wife when they shopped together. These are some of the practical difficulties which salespeople have, and upon which the experts in the store have a great deal of specific information.

The 300 salespeople told us how they handled the difficulties. The result was "How to Sell at Retail" the richest body of specific methods of handling specific selling problems in the department store field that is to be found anywhere. And the significant fact is that this information came out of the experience of the expert people in that profession. These methods had never been collected in print, because nobody had ever taken the trouble

to interview the experts. All that was done was to organize this material and present it in readable form. It was really the contribution of the salesmen on the floor.

Getting Data from Expert Salesmen. This points the way to the method that should be used in every sales organization. An organization of 100 salespeople does not need to go outside its own ranks to find all the material that any young salesman needs in order to do his job successfully. A national organization will find one man in Omaha who has an excellent method about which he has never told anybody because nobody has asked him. There is another man in Birmingham who has some excellent methods, and still another in San Francisco who has fine methods of meeting difficulties about which the organization has no knowledge. These men have been given no opportunity to talk about their methods of meeting difficulties except at conventions, and at conventions few have an opportunity to talk.

By this method anywhere from six to ten different methods used by different men to handle each difficulty can be collected. When these are pooled and put together under one topic and then given to the new men in the field, it is possible to say to them, "Here is the way our expert people handle these difficulties. Try them out and see which of them will work for you."

This procedure is thoroughly logical, and has proved to be so excellent in practice that it is amazing that it is not more often used. It is one of those simple things which are so obvious that we let them go by. The principle is not new. It is used unsystematically whenever we get salesmen together, put up a problem to them and ask this one and that to tell what he does. The method should be used more systematically. Someone should be employed to collect the information through interviews, write it down, and put it into mimeographed or printed form.

It is seldom necessary to interview more than thirty people on any point. When 110 people had been interviewed on seven difficulties, forty-five ways of handling the seven had been secured, or an average of about seven suggestions to a difficulty. Of these forty-five all but two were secured out of the first thirty interviews. The others repeated the first thirty so that all that was secured from the additional eighty interviews was two points. Considering the expense of employing people to conduct interviews, these two additional points were not worth the time. One can be certain that with thirty interviews on each difficulty one gets about all there is to be said.

Methods of Handling Instruction about the Product. One of the weaknesses of salesmen is their lack of knowledge of the product. In collecting information about a product it is advisable to study it under four heads. For instance, the American Radiator Company asked the following questions regarding the Arcola boiler:

Uses: What are the uses of this boiler?

Construction: What is the construction of the boiler? How is it made?

Talking points: What are the talking points of the boiler, both in terms of what it can be used for and in terms of the competing boilers?

Objections: What objections do you have to meet in selling this boiler?

If one is not selling boilers but is selling life insurance policies, the same outline is needed. One asks, What are the uses of the policies? What

human needs do they satisfy? How are the policies constructed on the basis of actuarial and mortality tables and other factors? What are the talking points of these policies, and what are the objections that can be raised to them?

What holds for boilers and life insurance policies holds for anything that is sold.

Sometimes in a highly technical business, such as that of the American Radiator Company, it becomes necessary, not only to know the talking points of the product and the objections to it but in addition to know the facts and principles of heat engineering which will explain why the construction of the boiler is effective, why the talking points are good, or why the objections are correct or unsound.

When salesmen are given a course in the theory underlying the product by a technical man in the organization the course is likely to be too theoretical; but this difficulty can be met by a very simple procedure, as follows: If one works out the methods of construction of a product, its talking points, and objections, and asks the question *Why?* after each one, he is carried back to the theoretical principles. For instance, if a talking point of the Arcola Boiler is that it is economical in the use of fuel, and if one asks the question *Why?* he will get an answer in terms of certain facts and principles of heat engineering. And when this question has been asked in connection with every one of the points mentioned and for every product of the company—in connection with construction, talking points, and objections—we get a collection of heat engineering facts, which are all that the learner needs to know. Then when these are handed over to the heat engineering expert in the factory to give to the student, the training director can say, "This is what you are to teach the men." The result will be that the course of instruction in heat engineering will contain only practical points in the subject, if the expert will stick to his text. He is expected merely to work up this material into the best form for the salesman's comprehension, but he must not go outside it, and he must be certain to put it all in. The expert knows exactly what he has to teach, and moreover the student knows when he studies the theory that there are no useless facts included in the course. Everything included is of practical use.

Obviously, however, in a good many organizations it is unnecessary to teach much theory, because there is little that will be of use to the salesmen. In some cases salesmen's technique may be hurt by too much theory; but if this custom-made job-analysis basis is used, one can decide exactly how much theory salesmen can use.

To repeat, the first thing to do is to analyze the job, and the second thing is to collect all the methods of performing the different duties and difficulties under the job.

Organizing the Material in Form for Teaching. The third step is to organize the material in form for teaching. There are a large number of different methods. Teaching may be done through lectures, through books, through pamphlets, through schools and classes, through graphs, motion pictures, etc. These methods need no discussion because we know a great deal more about teaching than we know about job and difficulty analysis

and the collection of developing instrumental materials or about training on the job.

Problem of Developing Personality. As soon as teaching is begun, the first difficulty encountered is one which is not usually found in courses of study. This is the problem of developing personality. Personality is a great asset to salespeople. In general, success is equal to personality plus brains, although most of us are inclined to say that success is equal to two parts personality plus one part brains. Yet one of the most amazing things about all training in the art of salesmanship is that we have allowed the training in personality to become merely an incidental matter. It is sometimes handled by teachers and executives and sometimes it is not.

Many feel that salespeople should come to them with the right personalities. If they have them we are glad. If they do not have them, we merely "stew" about them. If they are very bad, we fire them. Not more than one executive out of five makes a more or less serious attempt to develop the personalities of his men. A good trainer, if he finds a man quite discouraged, tries to encourage him. If he discovers that a salesman is efficient, except that he is a bit grouchy and hard to get along with, he attempts to make him agreeable. If he finds that a man would make an excellent salesman provided he had greater personal force, he tries to tell him what to do to be more forceful. One out of five executives does make the attempt to do this sort of thing, but we should use a technique by which it is possible in a comprehensive way to develop a strong personality, particularly in those traits in which salesmen are weak.

Developing Each Salesman's Traits. Each salesman's traits can be divided into three classes: he has a number of qualities in which he is particularly strong, a group in which he is just average, and another group in which he is relatively weak. In getting a picture of how to develop this salesman, I should want to look at his strong points and build around those. Perhaps his great strength is his forcefulness of manner. In that case I should want to build everything around his forcefulness, and with this picture in mind I should concentrate most of my attention upon his weak traits.

The technique of developing personality is not so difficult, if one wants to do it and knows how. We cannot, to be sure, make a silk purse out of a sow's ear nor make a man who is spectacularly deficient in a trait superlatively efficient in that quality; but we do not find many people who are completely deficient in anything. It is certainly true that we can by training make a man stronger in a trait than if we leave him to himself. Traits have been worked out for life insurance salesmen, for secretaries, for educational directors in department stores, and we know rather well what are the traits which are conspicuously important in explaining the successes and failures of salespeople and others. Moreover, there have been collected informally a good many methods used by people in developing these traits, although few of these methods have as yet appeared in print.

Up to this point we have considered analysis, collecting material, its arrangement in teaching form, and the necessity for paying attention to the traits and qualities which the individual salesman needs. Much of this

material can be put over in classroom instruction, but stress should be laid upon another point that is absolutely essential in any training program.

Training on the Job. There comes a time when the project method—or what is more commonly known as training on the job, or field training—becomes an integral part of the training program. For instance, let us suppose that we have twenty men who are going to be life insurance salesmen. The first thing we do is to put them in classes for four weeks and teach them all that can be taught in class. After that has been done, they are by no means finished salesmen. They have to be trained on the job. They have to go out with other salesmen to see how a sale is made.

The first thing that training on the job includes is an analysis of the job by the teacher to see how he does it himself. The second step is to show the person how to do it. The third is to give him a chance to do it himself while the teacher is watching him; and the fourth is to correct his mistakes. Finally he is followed up from time to time, so that he may be instructed upon the fine points that were missed in the early training. These five steps—*analysis of the job* by the teacher, *demonstration* by the teacher, *trial* by the learner, *correction* by the teacher, and *follow-up* by the teacher—are necessary in any efficient training on the job. After a salesman has learned his material in class, then he goes out with a good salesman or coach who knows what he is going to do. The coach says, "Come along with me and watch me while I make a few sales." After the sales are over, the coach talks them over with the salesman and by this means the beginner learns some points. Then the coach says, "You take the next sale and I will watch." At this point the real education begins because the beginner learns more by one trial than he could by a dozen demonstrations without a trial. When the trial interview is over, the coach tells the learner where he has succeeded and where he has made his mistakes. Then he has him try another interview and another until he feels that he is reasonably well trained for making sales alone. After this the coach drops in on him from time to time as he sells, and has him come in to talk his difficulties over with him, until finally he has reached the point where it is not necessary to do this—if that point is ever reached.

Responsibility of Executives in Training. The final principle is that 85 per cent of the training given to salesmen rests squarely upon the shoulders of the executives in the line rather than upon the training department. The training department is very useful. It collects the material, arranges it, classifies it, and holds classes and conferences. All of this is entirely worth while, but, in the last analysis, it is the executive who is just above the salesman that must do the bulk of the training, if the training is to be done thoroughly and well. Therefore, one of the functions of the training department is that of training executives to train their subordinates. It is a very difficult job to get many executives to feel that they are responsible for the training of the men under them, and to get them to develop the technique of training. While there are a few executives who are born teachers, the majority of executives have not yet learned that their major function is to develop men rather than merely to attend to office duties and financial policies.

TRAINING THE SALES SUPERVISOR TO TRAIN

BY BYRON F. FIELD, *Superintendent Training Division, Commonwealth Edison Company*

What are the requisite characteristics of a good sales supervisor? Is it not true that in sales organizations most supervisors have been chosen because they have been especially successful as salespeople, or shrewd in making suggestions to the buyer, or of long experience in selling, or because they knew a great deal about the merchandise, or a combination of two or more of these factors? Is it not equally true that the average merchandise supervisor is concerned chiefly in increasing the quantity of his sales and, if he happens also to be a buyer, in getting goods which will sell well and make a handsome profit?

No salesman should be refused promotion to a supervisory position because he possessed these valuable characteristics; and every supervisor should be greatly concerned with the desire to increase sales and hence secure better profit.

Our problem is this: Is the salesman who possesses some or all the above qualities certain to become a good supervisor or, putting it more strongly, is he certain to become the best supervisor? The answers depend entirely on whether there are other important phases to the supervisor's job than those mentioned. The growing conception of the supervisor's function is that there are other decidedly important elements in his job, namely, his ability to work properly with and through his subordinates, his fellow supervisors, and his superiors.

We are all confronted with two situations. The first is: To what extent and in what way shall a salesman, who is being considered for a supervisory promotion, be tested as to his ability to handle people both through training and in day-by-day relationship? The second is: Assuming that we have a supervisory force deficient or unskilled in training salespeople, what method shall be employed to train the supervisors better to train their subordinates? This discussion will be concerned chiefly with the second problem. It should be said, however, that the work of training future supervisors to train would be very much lessened by a more serious consideration of ability to deal with and train other people, in deciding who is to be promoted in the first place.

The Commonwealth Edison Company maintains a number of electric shops and a force of house-to-house salesmen. Electric shops are maintained by the company in order to render the ultimate service possible by the introduction of such appliances to the public; to set a standard of quality to all electrical sales organizations in the community served and, of course, to create a greater demand for electricity—and to make some profit. One can see from this that the company must, quite naturally, be particularly sure that the sales remain sold, that the articles which are sold are useful to, and used by, the customer.

The General Training Program of the Company. Before going into the specific subject of training the supervisors to train, a few words about the general training program in the company might furnish a background. In this organization, as in any other, training of a sort has always been

carried on in every department. This has been largely informal. The methods employed, the duration of the period over which the training extended, and the success achieved, have depended largely on the initiative, ability, and personality of the individual or individuals in any department who conducted the training. Acting upon the supposition that no one individual possesses all the skills and traits necessary to make a good trainer, and that no one individual possesses all the knowledge which could profitably be imparted to the new employee, a training division has been installed in the industrial relations department.

The work of training may be conducted either on a centralized or decentralized basis. When the centralized plan is employed a large training staff of experts is built up in the central training office. Various members of this staff are assigned to conduct training for, and in, certain specified departments. This extradepartmental trainer theoretically brings into the department a high technical skill in the training necessary in that department. Under the decentralized plan the training office maintains a relatively small force, whose duty it is to draw out from the various departments in which a training program is undertaken the methods most useful in those departments. This company is committed to the second, the decentralized plan.

About 1926, at the instigation of the president of the company, three surveys were made. The first dealt with the attitude of the customers toward the company; the second, with the attitude of the employees toward the company and the public; the third measured the actual performance of the employees in dealing with the public from the public-relations angle. The results of the surveys showed that while the morale of the employees was very high and the desire to give good service was equally high, this desire was not sufficiently transformed into action. The customers were favorable to the company but not as warmly favorable as they naturally would be if the employees showed more actively their desire to give the best possible service. The evident problem was one of giving the necessary training which would bring out the best practices in dealing with customers.

The sales department was obviously one of the most important in which to carry on training. Before doing so, however, it was necessary to analyze those factors in an employee's performance which most affect the customer's attitude. A long scientific study had already been conducted on this subject, and a fairly definite agreement reached as to the relative weight of various factors. These were, in the order of their importance: *interest shown in the customer, quality and method of giving information to the customer, appropriateness of speech, politeness, and appropriateness of appearance.*

Conferences on Public Relations Factors. An employee of the company who had considerable experience as a teacher was given special training as a conference leader. This title is significant. He was then assigned to conduct conferences with the salespeople and supervisors in the electric shops on these important public-relations factors. He did not enter the electric shops department, however, as a teacher giving training on certain facts from a text; he entered rather as a questioner seeking opinions, information, and ideas about those factors from the people who were on the job day-by-day. Before any subject is discussed with the salesmen a similar meeting is carried on with

the supervisors on the same subject. This brought in the supervisors so that they felt the material was their material. Hence, when they carried on meetings they felt that they were discussing their own material.

When the subject of interest in the customer was taken up, the conference leader asked a large variety of questions to find out specifically what devices, acts, phrases, and attitudes had been found, by actual experience, to induce the most favorable customer reaction. The same or similar questions were asked of all the salespeople. The conference leader then put these answers together in writing in logical order. These agreed best practices were then turned back to the people for still further discussion and comment. When they had finally been approved by the salespeople, their supervisors, and their department head, they were set up as the standards of personal service of the electric shops. Incidentally, a similar program was installed in over a dozen departments.

Service Sampling. From the beginning it was felt that there should be some definite measuring stick to show to what extent the performance of the salespeople with the customer had been improved, as the result of the meetings and the standards of personal service which were developed in them. This measuring stick took the form of service sampling. Service sampling consists of sending make-believe customers into the department to carry on what to the salesperson is a normal customer transaction. The service sampler asks the same questions and reacts, to all appearances, in the same way as any other customer. At the conclusion of the make-believe transaction the service sampler, in private, prepares an analysis of the entire occurrence. In it the sampler rates the salesman numerically as to the degree of satisfaction produced by the various factors entering into the contact.

To be specific, the factor of interest in the customer is broken up into as many of the component items as possible. In rating the salesperson's performance the degree to which he has shown interest in the customer, based on this agreed standard, determines his rating on this factor. He is similarly rated on the way in which he presents his information, on his speech, his politeness, the appropriateness of his appearance. Of course, the identity of the sampler as a sampler must always be hidden, otherwise the value is lost.

In this company, because of the determination to distinguish between service samplers and so-called "spotters," employees making a low rating on a service sampler's report are not identified. The material written up about such interviews is used for general illustration rather than for individual discipline. Cases of "distinguished service" are identified, and the person and department notified.

Sampling has now been carried on over a period of four years and an improvement of over 35 per cent has been made in the electric shops. At first the sampling was confined to limited periods; later it was made continuous as a part of the activities of the public relations department.

Shop Meetings under Supervisors. While the original meetings on the subject of public relations, in the many departments where the highest percentage of customer-employee relations existed, were carried on by an outside staff man, the intention from the start was to turn over as much of the training as possible to the supervisors in the departments concerned after the original series of meetings had been concluded.

In line with this determination it was arranged to have monthly follow-up meetings on public relations matters conducted in the electric shops by the supervisors themselves. In the electric shops, as in other departments, the supervisors who were to carry on the follow-up meetings were called together for a discussion of objectives and methods to employ. After having been given an outline for discussion and lengthy instructions on methods the supervisors started in

The events which followed proved that no matter how well-meaning the supervisor may be he cannot carry on first-rate discussion meetings without a considerable amount of special training along that line. A supervisor who acts and reacts very rationally under normal circumstances frequently becomes nervous and confused in leading a discussion meeting. In more than one case the supervisor read sections of his outline, which were intended for himself alone, to the group. Another common tendency of the supervisor was and is to ask a question and, having received a one-sentence answer, close off all further discussion by answering the question himself at much length. This can be avoided only by considerable training and experience.

These incidents were valuable chiefly because they showed clearly two things. The first was that there must be much training of the supervisor before he starts training his subordinates. The second was that, for the first few meetings held, a staff-training representative should be present to enter into the discussions occasionally, if necessary, and make notes for discussion with the supervisor after the meeting.

It will be seen that this entire training enterprise was based on the original survey which indicated certain deficiencies. The survey was made, the outstanding deficiencies which might be corrected were analyzed, the meetings were held for the common discussion of the best methods of overcoming the difficulties. Before, during, and after the meetings surveys were carried on to determine just what improvement was resulting from the training.

For purposes of comparison it is fortunate that there was undertaken with the electric shops' salespeople another training procedure, quite different both in methods pursued and general set up. Partly as the result of the success of the public contract training program, the management of the electric shops asked to have general job training set up in the department. The first step to effect this was to send a staff investigator to the electric shops. While there, he was to make both activity—and difficulty—analyses. It was early determined that job training should include instruction on the proper use of the sales ticket, on the information necessary about the various articles on sale, and on the technique of salesmanship.

The staff representative conducted this study as a salesman on the job, as an interrogator both of salesmen and supervisors, and as an observer. In making the study he listed the difficulties confronted as nearly as possible in the order of their importance and frequency. In preparing material on merchandise information he not only secured the fundamentals furnished by the manufacturers' representatives, but also those other factors about which average customers are curious. In preparing the sales technique manual a group of people studied the mass of literature available and its application to the electric shops' situation. As a result of these studies three manuals

were prepared. One dealt with the sales ticket. The second, on merchandise information, devoted a chapter to each class of appliances sold. The third manual, on sales technique, considered all those factors with which it is felt the salesman should be familiar.

Training work, aside from the follow-up conferences on the specific public relations angle of the work, was divided into three general parts. The first is the vestibule school, in which new salespeople are trained briefly on the essentials with which they should be familiar immediately, while at the same time starting on their work as salesmen. The second is the general training conducted with all salespeople by supervisors. The third is training of the supervisors to train.

In the public relations training the conference leader entered the meetings with a skeleton outline which formed the basis of the discussion; in the job-training meetings the leader entered the group with a definite manual which contained the basic body of material to be studied.

The Electric Shops Training Supervisor. Before the manuals had been completed for use the question of who was to have general supervision of the training in the department had to be answered. To carry out the plan of decentralization it was determined to choose from among the supervisors within the sales department a competent individual who would carry the title of electric shops training supervisor. Much time and thought was given to his selection. He needed to be patient, to have a high degree of cooperativeness, ability to assimilate proper educational methods and disseminate these to the supervisors within the department who were to act as coaches under his instruction. He had to be an individual with enough background of sales and supervisory experience to give him and the other supervisors a fellow feeling in their common problems. At the same time he had to have a genuine enthusiasm for training. After a careful consideration of every supervisor in the department by the department head, and one or two others, a candidate was selected.

This sales training supervisor has a variety of duties. His desk is the clearing house for all sales training material. He personally conducts vestibule school meetings with new employees; largely trains the supervisors to train; and, by sitting in at their meetings, offers suggestions as to improvements in material and technique.

Obviously the immediate function of the company training division was to help the sales supervisor to become a specialized trainer. This was done by a long series of informal discussions, and by sitting in at meetings he conducted, which were later used as a basis for the discussions. There was daily personal contact with the developments in the electric shops, but the major part of the execution was left to the trainer there. The electric shops training supervisor has been discussed at such length because his is the key position in the program. Provided there is a sales force of any considerable size, a training supervisor, selected from the group, who stays on the sales payroll as staff advisor gives the best possible medium for carrying out the general training program in such a department.

Drawing on Employee Experience. During the time when the staff investigator was making his difficulty—and job—analyses in the electric

shops, and during the entire development of the training program, the supervisors were called upon for suggestions. When the manuals were completed they were felt to represent the approved ideas of these people themselves. The supervisors were then called together in a meeting and the future program carefully outlined to them. It was indicated that from then on they would be expected not only to conduct training meetings with their salespeople, but to take part in meetings for the improvement of their own technique in training.

The material upon which these supervisors are being trained as to the best methods of training their salespeople has been prepared by the company training office from a combination of experience, observation, and the best literature in the field. This material is being used by the electric shops training supervisor in his coaches' meetings. Incidentally the supervisors, in their capacity as trainers, are referred to as coaches. This training material goes in considerable detail into the methods which are most useful in holding meetings of employees. Practical demonstration meetings are held with supervisors before the final material is presented.

Department heads have been found frequently to require even more training on how to conduct discussion and training meetings of supervisors, than supervisors in their meetings with salespeople. They must be given the same kind of advisory assistance.

Regardless of his personality the department head or supervisor, with very few exceptions, will always dominate a group consisting of his subordinates. In a training meeting, however, the fundamental idea is to draw out information from the group members. In order to do that the group leader must learn how to subordinate his own desire for self-expression, and how to get the most general participation. This is not an easy task and cannot be accomplished until after a number of meetings have been held, in which the company training man observes the methods employed and offers suggestions for improvements after the meetings. So far it has been found that this method can be used successfully both in training department heads to hold discussion meetings of supervisors, and for supervisors in holding meetings with their subordinates.

Testing Results. Just as in public relations training some sort of measurement had to be set up, so in job training various devices for testing results were provided.

To test the performance on preparation of sales tickets a chart for the compilation of errors on sales tickets was prepared. On it were noted a variety of possible errors. When an error was discovered on a sales ticket a copy of that ticket was routed to a desk where the error was checked opposite the name of the person who made the mistake. This check obviously was direct. As soon as any individual had made more than the minimum number of mistakes he was called in for special additional training on sales tickets. Such a call, being partially disciplinary, quickly took on a high stimulative value.

The check on merchandise information is indirectly reflected in the per cent of articles returned by customers after purchase. Information given is also noted in the service samplers' reports.

The check on sales technique is reflected in the gross sales, and per cent of return sales columns in each individual's performance record. Absence

and tardiness, and any minor infraction of regulations, are also noted as indicating the frame of mind toward the job. Quarterly reports are prepared by each supervisor giving the rating of each of his subordinates. This proves a very good cross-check because a supervisor finds it rather embarrassing to insist to the electric shops trainer that a certain salesman should have considerable additional training when at the same time he is rating that salesperson as "superior." In addition to furnishing a check of their performance the various reports give a very definite stimulus to the interest which the salespeople take in the training meetings, and in putting the ideas developed there into practice. Many feel that this is the more important service given by the various checks and by the service sampling reports.

Monthly reports by the supervisors on the meetings which they have conducted, the subjects which have been discussed, and the salespeople who have attended, are sent to the electric shops training supervisor. He includes copies of these reports, together with a list of the meetings he has conducted, of the coaching he has given the supervisors as trainer, and of the general progress of training in the department, in his monthly report to his department head and to the training office of the company.

In addition to what must seem an extremely comprehensive training program there was also started at the earnest request of the head of the department, a series of supervisors' meetings conducted by the head of the department. These meetings, of course, are for the discussion of the various elements which go to make up the supervisors' responsibilities, duties, and functions in addition to those relating to training.

All of us are confronted with a very definite problem. We have supervisors who have been promoted to their positions because they were good salesmen; not because they were good trainers. We must now aid them in the best methods of transmitting the skill they developed to the people whom they supervise. It is certain that the time will come when the natural ability to train, to work with, and to help others, will play a more important part in selection for promotion. Until then we must be more than ever concerned with the methods to use in making quasi teachers out of salespeople. Even after the millennium is reached it will be recognized that training subordinates is a major function of supervision, and that the process, although greatly improved, must continue. We will always have with us the problem of the training of the trainer to train.

RATING SCALES FOR IMPROVING THE EFFICIENCY OF SALESMEN

By H. G. KENAGY, *Assistant Manager, Life Insurance Sales Research Bureau*

Rating scales, as we find them in the business field today, are the least scientific of the measuring instruments in use, and give little immediate promise of becoming comparable in objectivity or accuracy with other types of psychological measurement. At the same time they are the most widely used. Personnel workers, and even line executives, who do not attempt to use intelligence tests, for example, find no apparent obstacles to devising

rating scales for almost any purpose. Psychologists and statisticians who have attempted to devise rating scales for practical use have generally become thoroughly disgusted or discouraged over the possibility of developing reliable—i.e., scientific—instruments, but the business man has not been deterred by any lack of reliability; he has no scientific conscience or consciousness. Yet it is not exactly a case of fools rushing in where angels fear to tread. The fact seems to be that even the most unscientific rating-scale efforts have achieved worth-while results, and practical experimenters have not been willing to quit the field merely because they have no high positive co-efficients with objective criteria or other proof of reliability.

In other words, rating scales are highly popular instruments and are likely to be permanent additions to the personnel tool chest. Yet it need not be assumed that we must accept the present unscientific character of rating scales as final and inevitable. Most of the present troubles arise from the fact that rating scales are used by persons without scientific training in psychology or statistics. They do not think naturally in quantitative terms about human traits; they do not even agree with each other as to the definition of the most common traits. Rating results can be made increasingly reliable, but the process will necessarily involve a long period of educating the raters in the fundamentals of rating scale theory and technique. If the psychologists and statisticians will be patient, and lend a hand in this educational process, the next generation of executives may talk as intelligently of distribution curves, reliability coefficients, percentiles, etc., as any scientific worker could wish.

Granting the present unscientific character of rating scale practice, what value have such scales as can be used and how are the scales to be employed?

Rating scales have four, perhaps not distinct, but distinguishable uses:

1. To provide a better basis than is generally in use for judging the salesman's efficiency on the job.
2. To serve as a guide for systematic training and supervision on the job by field managers or supervisors.
3. To supply data on the training needs of the sales group, thus indicating the requisites of the training program.
4. To supply the individual salesman with a picture of his job in terms of its specific requirements, so as to enable him to follow intelligently a program of self-development.

A rating scale which is to be used for these purposes—and a single scale will serve all four—must necessarily be built upon a complete and detailed analysis of the salesman's job. We cannot, therefore, have a single rating scale universally applicable to all sales groups; we must have a different scale for each particular selling job. If within a single company there are two or more different types of sales work, then two or more scales must be prepared. Every rating program which is successful must be a direct outgrowth of the specific situation in which it is to be used; a scale borrowed from the outside, even from a single concern, will have little value no matter how successfully it may have been used elsewhere.

Measuring the Intangibles. The use of rating scales for *judging efficiency on the job*—which was our first purpose—is an admission of the fact that such

objective measures as we now have—volume of sales, per cent of quota obtained, distribution, cost to sell, etc.—are not sufficient to give us a finally reliable measure of the individual salesman's worth. Even when we have achieved the utopian dream of scientific quotas and reliable standards for fixing the salesman's tasks, there will still be a group of intangible factors, contributing indirectly and in the long run to the total results, which can only be evaluated by some sort of rating scale. Let us measure by quantitative methods all of the factors in sales efficiency which can profitably be so measured, taking into account sales possibilities and other conditioning elements; we shall still have many intangibles, even in the specialty salesman's job, which can be evaluated only by personal judgments.

Job analysis ordinarily develops three kinds of information about the salesman's task: (1) specific duties and responsibilities—the skills required, (2) knowledge or information needed, and (3) the personality traits necessary or desirable. Many elements under (1), and perhaps under (2), can be subjected to quantitative measures; the elements included under (3) must be left almost wholly to subjective estimates. If the salesman's task has been *carefully defined* in such terms as "required calls per day," "percentage of outstandings on collections," "number of demonstrations per week," "number of goodwill calls to be made," etc., in addition to the usual measures of sales results, and if the salesman's store of needed knowledge has been tested, most of the questions involving *what* and *how much* are answerable without a rating scale, but we still have the questions which begin with *how well*. We can use absolute figures in recording the number of calls made, the cost per unit to sell, the percentage of possible outlets sold; we must use relative terms in recording the salesman's ability to build goodwill, his reaction to supervision, the effectiveness of his demonstration methods, and similar items.

Perhaps it should be pointed out, in passing, that there are many elements of the sales job subject to measurement in quantitative terms on which, because of their relatively minor importance, actual records need not be kept. It is possible to record, for example, how many display signs a salesman places each day in the stores of his customers, provided that is a required task, but such a record might not be worth the cost. Besides, the locations in which the salesman placed those signs, and the manner in which he presented them to dealers, are facts of greater importance than the number he succeeded in disposing of. Therefore it is proper and wise to include such elements on the rating scale, asking both the questions *how much* and *how well*.

Use of Rating Scale as Guide in Training. In most sales organizations, the use of a rating scale to judge a salesman's efficiency and therefore to classify him for compensation purposes or promotional possibilities, is the primary and all-important use. Of much greater importance is the second use mentioned above; to serve as a guide for systematic training and supervision, on the job, by field managers or supervisors. For obvious reasons, which will be discussed later, the ratings on salesmen in one group are not strictly comparable with the ratings on salesmen in other groups unless the same manager has done all the rating, for our rating scales are not yet reliable measuring instruments. Therefore, the use of rating scales as accurate

measuring devices must be considered secondary in importance to other uses—at least until better scales can be employed.

Inaccuracies and the lack of comparability do not enter as deterring factors when we use rating scales to promote systematic training and supervision. Each salesman can be considered by himself and his development definitely planned, regardless of how his fellow salesmen are rated or whether he has been rated generally too high or too low. Our interest is in the rating on specific elements of his sales work, and no salesman is so perfect in every phase of his job that some need for training will not show up.

Assuming that the work of job analysis has been properly done and that the rating scale calls for judgments on how well the salesman performs specific elements of his task the rating record should indicate clearly to the supervisor the various weak spots in the salesman's working equipment. It is therefore the starting point in a program of systematic development of sales ability. Naturally we must have the necessary training material covering each element of the job, and we must have supervisors who have learned how to teach—but that is another story.

Training Needs of the Whole Sales Force. As a natural corollary or supplement to the use of a rating scale in training on the job, the scale will supply to the sales manager or his training department the data from which to discover the training needs of the sales force as a whole which require special attention. Suppose, for example, that the rating results secured by a food products concern uniformly show that their salesmen are rated low on: (1) knowledge of company history and policies; (2) ability to interest dealers and clerks in pushing its brands; (3) attention to slow-moving brands; (4) merchandising suggestions given to dealers; (5) adjustment of complaints and errors; (6) analysis of dealers' needs; (7) enthusiasm over the company's reputation and character, etc., the sales manager would know that his sales force needed training in methods of building goodwill and he could take steps to see that the most effective methods were collected and taught to his men. Again, if the rating records show lack of attention to new outlets, little progress in building distribution on special items, heavy casualties among old customers, weakness in handling the sales interview, etc., it would be clear that the remedy lies, in part at least, in developing certain personality traits in the salesmen—aggressiveness, tact, industry, earnestness, and self-confidence.

Rating Scale Used to Analyze the Job. The fourth purpose which rating scales can serve—that of supplying the individual salesman with a picture of his job in terms of its specific requirements, so as to enable him to follow intelligently a program of self-development—has seldom been recognized, though it is perhaps second in importance only to that of promoting systematic training.

It is often true, unfortunately, that the salesman has never been given a picture of his job except in the most general terms. He has not been given an analysis of his duties, nor shown the many elements which contribute directly and indirectly to his success. Quota, collections, sales talks, demonstrations—those things have been dinned into his ears day after day, but ability to plan his work, promptness and accuracy in making reports, respon-

siveness to sales suggestion, goodwill building, cooperation with other salesmen, tie-up with company advertising, and similar factors have not been presented in terms of the specific activities which go to make up the day's work and therefore ultimate success on the job.

Yet salesmen crave just this sort of information. They welcome the fact that they are being judged on a definite scale rather than on the usual indefinite basis of general worth. They like to feel that their work is analyzed point by point, and credits matched against criticisms, because otherwise a single outstanding weakness usually causes lack of consideration of many good points. But they want to know the basis of judgment. If they are kept in the dark, they are inclined to view the rating system with suspicion and distrust, they try to hide their mistakes and cover up their weaknesses with alibis.

Experience in firms which have offered the rating scale to their salesmen as the basis for a program of individual development has been altogether favorable. Some managers have had their salesmen rate themselves and then bring their ratings for comparison with the managerial judgments. Differences were discussed and the reasons for low ratings on particular points explained. Then the managers suggested steps to be taken to improve the ratings. The net result was better directed effort on the part of the salesmen and a stronger bond of confidence and goodwill between each salesman and his manager.

Every serious-minded salesman is ambitious to improve his position—in salary at least. The better he understands what is expected of him, the easier it is for him to measure up and the more interest he will show in self-development. The more specific we can be in setting standards of action and in defining his tasks, the greater the effort he will put forth in seeking to meet the requirements.

Intelligent Use of the Scale. I have tried to indicate that the value of a rating scale arises from its usefulness in securing better judgments of the efficiency of salesmen and in promoting the work of developing men. Both of these functions rest primarily upon the field executives and supervisors. It follows, therefore, that a rating scale is of little value unless it is used intelligently by these men, and unless it is tied up with a well-defined training program which has their interest and support. Educating raters and securing their active cooperation in the follow-up training program is an administrative task which presents some practical problems. With these problems we shall deal briefly:

How to get a rating scale used is the first problem which confronts the sales manager or his personnel department. The sales organization is far flung; the field managers or supervisors are running their own little organizations without much supervision, usually, and without much contact with other managers or general office departments. They are practical men, spending their time chiefly in handling matters of administrative detail. They have had no training in personnel management; they have given little thought to personnel problems except in the handling of specific cases. Finally, they are busy. When we start out to introduce a rating plan which these men are to use, these are the facts which we must keep in mind.

We know, therefore, that the rating plan must be simple, easy to understand and to use. The items on the scale must be couched in familiar terms—the terms they use, so far as possible. Furthermore, the scale must be short, or be so easily used that it takes little time. Field managers refuse to be bothered with anything which appears to take much time from pressing duties to do a job which, to them, is already being fairly well handled. Finally, the rating phrases or judgments must be in terms which the managers habitually employ, or so similar as to cause no conscious mental adjustments.

Fitting the Scale to the Situation. Most of these practical conditions are met by building the rating scale to fit the specific situation, using job analysis data to select the actual items for the scale. This insures that the managers will understand the terms used, and also gets away from the common tendency to rate on abstract qualities such as adaptability, leadership, convincingness, resourcefulness, etc. However, if a rating scale is inaugurated in advance of thorough-going job analysis, abstract terms such as these can be used with fairly comparable results if defined in terms of job activities. For example, a rating on "resourcefulness" can be made fairly useful by indicating the things which a resourceful salesman does, such as: discovers ways of overcoming new objections and difficulties; originates and tries out new selling ideas and merchandising plans; makes suggestions to others, etc. Leadership, similarly defined, would mean: takes the lead in conversations; dominates the groups of which he is a member; inspires other salesmen; promotes group cooperation.

To meet the requirements of brevity, some of the minor elements of the job may have to be omitted. It helps, also, to group or classify the items under general headings, thus giving the appearance of brevity. Actual judgments can be secured on a hundred specific factors if only a small number of final judgments are required.

Method of Recording Judgments. The task of determining what method is to be used in recording opinions, is at once a highly important and most difficult one. We must keep in mind the terms which field managers habitually employ in passing judgments and at the same time we must try to insure as much scientific usefulness as possible. We do not have to use the manager's somewhat crude and often ambiguous terminology, of course, but our terms must be capable of ready translation into his own thought media. Continuous educational work will gradually make it possible to introduce a more nearly ideal system, but in the beginning our job is that of refashioning the manager's common-sense methods into a fairly reliable scientific instrument—leaving all the common-sense ear marks sticking out conspicuously.

Our chief difficulty arises in connection with the method of recording judgments. Field managers ordinarily lack the capacity to think in quantitative terms about personal traits and they do not understand what is meant by a normal distribution. Furthermore, many managers lack wide experience with salesmen outside their own immediate groups with which they can compare their own subordinates. Standards of performance therefore vary widely from one district to another. When managers are asked to rate their salesmen using the time-honored phrases "superior," "above average," "average," "below average," and "poor," they will place less than ten per cent in the lowest two classifications, regardless of caution in the

instructions that a normal distribution calls for approximately thirty per cent in these groups. There will also be the usual result of some managers ratings uniformly low and others uniformly high. Of course these differences can be corrected by available statistical methods, but the problem of getting a wider distribution of ratings within a group needs attention at the source.

Professor Forrest A. Kingsbury of the University of Chicago, after evaluating experimentally the various types of rating methods—man-to-man comparisons, graphic scales, numerical judgments, and colorful adjectives—adopted the five degrees, mentioned above, in which terms managers habitually pass judgments on their subordinates, and secured a satisfactory distribution of ratings by using the following definitions, which are not only practical and comprehensible, but theoretically defensible:¹

The central rating of 3, or average, is defined as meaning that the employee "meets reasonably satisfactorily the recognized departmental standards in respect to this trait." Every manager knows exactly what this expression means. It helps to impress upon him that a rating of 3, or average, is in no way a slur, but is the normally expected rating, and that it is the 4's and 5's, the 2's and 1's, which are departures from the normal.

A 2 (below average) rating means that the employee is "deficient enough in the trait under consideration so that he has had to be warned, criticized, or otherwise spoken to about it." This again constitutes a perfectly objective and reliable criterion of moderate deficiency. It is explained that this does not mean threatened dismissal, but is merely a warning signal, to keep the employee under observation. The manager is directed to account for all 2 ratings by indicating whether they mean inexperience or some other cause.

A 1 (poor, unsatisfactory) rating means that the employee is so seriously deficient in the trait that, if it is an important one, he is under consideration for transfer or dismissal.

Of the two superior ratings, 4 (above average) is defined as meaning that the employee "stands out above the general run of the employees of the department in respect to this trait." When asked to name the outstanding employees, the names which occur to the rater without hesitation are almost invariably those of the 4 and 5 men.

A 5 (superior, exceptional) rating means that the employee stands out so conspicuously from even the 4 men that he ought to be distinguished from them. They are of course, few and readily recognized and are ordinarily candidates for early advancement.

Two facts are impressed upon every rater: first, that it is the employees who rate above average or below average that are of most direct concern to the institution, the former because they are potential promotional material, the latter because they suggest some failure in selection, placement, training or supervision; and, second, that those above average or below average are fewer in number than the average, just because they represent exceptions and not the general rule.

"Yes" or "No" Rating. Another type of rating method which has great possibilities is one which avoids all gradations of judgment and requires instead yes or no ratings on specific points. Such a scale gets away from descriptive words and phrases altogether, recognizing that the subjective

¹ *Journal of Personnel Research*, vol. IV, No. 1, p. 2, May, 1925.

standards on which raters make their judgments are inconstant and unreliable. It presupposes, however, the setting of objective standards, the fixing of such specific requirements on the job that yes or no answers are possible. It avoids the "how well" type of questions, but sets the standard of acceptable accomplishment and asks whether this standard has been reached or not.

Such items as the following, adapted from a scale used by a large food products company, will illustrate what I mean:

Does he follow the sales plan?

- a. Always opens and uses sample case.
- b. Sells the full line.
- c. Builds assorted order around a leader.
- d. Strives for initial sales to build distribution.
- e. Uses pencil and figuring pad in sales presentation.
- f. Ties up with company advertising.
- g. Checks the dealer's stock.

If the salesman does these things, check marks would be recorded in the "yes" column on his rating record. There may still remain questions as to how thoroughly he does them, but there are likely to be enough "no" ratings to take the full time and attention of the manager in training and supervision.

Rating as an Administrative Device. It will be clear from all the foregoing that rating scales are to be considered more as *practical administrative devices* than as scientific instruments, though efforts to improve them as psychological measures should not be abandoned. As administrative devices, they have two general functions: (1) to supply measures of efficiency to supplement our present unscientific quotas and other faulty standards of sales success; and (2) to furnish the basis for systematic and intelligent development of sales personnel. Both of these functions are best served if the rating scale is developed for the specific situation from a careful job analysis. This makes possible a scale prepared in terms of the job and therefore understandable by those who are to use it.

When inaugurating a rating system, it is important to appraise the conditions which will determine its successful use. The intelligence and capacity of the raters must be gauged as well as their habitual modes of expression in judging subordinates. What is needed first is a scale that will be used rather than one that is technically good. Careful definition of the common terms used by line executives will make possible fairly reliable results for statistical purposes, but the educational purposes served are even more important. Once the interest and support of the organization is secured, improvements in the rating plan can be constantly introduced. But we do not need to await perfection in rating technique to take advantage of the excellent opportunities our present scales afford for systematic training of salesmen, both individually and in groups.

COMPENSATION OF SALESMEN

By C. K. WOODBRIDGE, *Vice President, Remington Rand, Inc.*

All agree that as we progress, new conditions constantly confront us. Therefore, with changing international, national and local conditions, there

follow continual changes in the activity of business enterprises. Business meets these changed conditions by readjustments in methods of manufacture, management and distribution. As a result of this, problems in compensation of salesmen will always confront us and all kinds of compensation plans will be subject to constant readjustment if suitable reward be given for effort.

A brief summary, showing the kinds of plans already in use, follows:

Commission Plans. *Straight Commission.* Paying salesmen a certain per cent on sales.

Sliding Commission. Paying salesmen a given commission on business up to a point, automatically increasing the commission rate as definite sales totals are reached.

Group Commission Plan. The seller's merchandise is divided into groups, each carrying a different per cent commission for the salesmen.

Commission and Drawing Account, Either Guaranteed or Applied against Earnings. In case of guarantee it may be paid only if certain tasks are daily performed, such as:

Sending in daily reports.

Sending in names of prospects.

Sending in evidence that demonstrations or calls have been made.

The commission plan places the sales expense and risk on the salesman. Many concerns could not start or stay in business if it were not possible to hire on commission. They would be unable to finance their selling. In practice, the plan develops a tendency to oversell. Calling on all prospects is neglected. The relationship of salesman and house is not close. Too much money is made in good times—too little in hard times. Salesmen say that they prefer it provided the per cent is as large as they think it should be, since it does not limit earnings.

To the above commission plans can be added the payment of expenses.

Salary Plans. *The Straight Salary.* This plan is probably used by 50 per cent of all concerns. The man with the fixed income, having faith in his house and a quality product, works as a partner in the business and increases goodwill for his firm. The salesman obeys the rules of the house in selling its goods. The plan lacks, in the minds of a great many, proper incentives for better than ordinary performance of duty.

Salary and Commission. This is a combination of the two most widely used compensation plans. It is favored in times when selling is difficult. It takes care of the salesman's fixed obligations. By it a salesman is supposed to profit through his industry.

Salary Plus Expense against Commission. In this plan, salary and expense are deducted from commission earned on sales and if there is an excess it is paid to the salesman. This plan puts a check on traveling expenses.

Salary and Commission on Sales over a Certain Amount or Quota. Making quota is an exciting game and, if the rules are fair and quota not unreasonable, it is entered into with great enthusiasm by salesmen.

Salary and Percentage of Savings Plan. In this plan the company sets a certain percentage figure to cover the expense of each salesman's territory. and, by increasing his sales or reducing his expenses, the salesman can effect

extra earnings. Each salesman is given a sales quota for his territory. Each one is similarly given a sales budget based on an analysis of the cost covering this territory in the past and modified to meet present costs.

If the salesman's quota is \$200,000 per year and his salary plus expense budget is \$6,000 per year, his given expense rate will be 3 per cent. If he increases his sales to \$250,000 he will earn an extra 3 per cent on \$50,000 or \$1,500.

If he keeps his sales at \$200,000 and reduces his total expense to \$5,000, he will earn an extra \$1,000.

Salary, Commission, and Bonus. This combination introduces the bonus or premium in recognition of excellent or superior service.

Drawing Account and Commission or Per Cent of Profits. In some instances, a drawing account takes the place of salary and is applied against commission or a per cent of profits accumulated.

To the foregoing may be added methods of financing expenses.

Bonus Plans. The introduction of an extra allowance for sales effort of excellent or superior character based on dollar sales, or units of sales, or service rendered has created many forms of bonuses. These include:

Bonus on Special Features. An amount is paid for pushing, for instance, packages more than bulk goods, a special item of profit to the manufacturer, etc.

Bonus on Net Profits. Salesmen are given a per cent on net profits.

Bonus on Total Sales. This plan encourages volume building, sometimes at the expense of profit.

Bonus on Quota Excess. A quota is assigned to each man which represents what he ought to sell normally and a bonus is paid for all sales in excess.

Bonus on Low Sales Costs. A reasonable cost of selling is established, and a bonus paid to salesman if his cost is less.

Bonus on Service to House. A bonus is paid on estimate of constructive value of salesman's work, as for example:

1. New accounts opened.
2. Calls made.
3. Sales of profitable goods.
4. Answering correspondence, etc.

Bonus on Increased Efficiency. This is designed to correct weaknesses and develop sales ability. Marks are given for:

1. Integrity (indicated by letters of complaint).
2. Aggressiveness (shown by new accounts opened).
3. Industry (number of calls made).
4. Company interest (indicated by expense account).
5. Salesmanship (sales at a profit).

The bonus fixed by the management is divided on the average efficiency marks.

Bonus on Promotional Works. This is paid for dressing windows, opening up new dealers, selling "hard nuts," etc.

Bonus on Calls. This is paid on each new call and each repeat call.

Bonus on Branch Office Sales. This plan promotes cooperative work. The bonus is paid on total sales over quota for branch and prorated among salesmen.

Task Plans. The definition of compensation as a suitable return for the expenditure of energy calls for consideration of jobs or tasks and consideration of what performance is worth.

Obviously one can develop a great many new compensation plans by adding task as a factor. Since the salesman spends a greater portion of his time, in preparation before the sale and in follow-up after the sale, than in the actual sale, a plan of paying for the task performances and giving bonuses as incentives for excellent performance is of great interest. Some of the tasks used are:

1. Daily calls.
2. Follow-ups.
3. Demonstrations.
4. Putting up advertising material.
5. Collecting accounts.
6. Specific dollars sale total.
7. Sales over and above the amount set in the task.

Payment for the tasks performed may be accomplished through commission, through salary, or through fixed amounts for each task. Its introduction involves a method for recording tasks performed and computing their value.

Properly to measure the results or value of a salesman's work, it is necessary to fix a value on each of the duties to be performed and to credit the salesman when he has performed those duties. The value of the credit must be determined. For every dollar sold and every job done, points having a certain value should be given. Penalties should be fixed for not doing the things the company wants done. The value of a point having been determined, the salesman's salary should represent, in points, the performance of his task. If .004 is the value of a point, 5,000 credits or points would be necessary to earn \$20 a week.

Factors Used in Giving Points. Basis of reward one point per dollar sale

Credit for Selling Desirable Products.

1. Easy selling advertised product.
2. Products offering double net profit.
3. Products offering triple net profit.
4. Products especially hard to sell.
5. Products that have very high repeat qualities.
6. Products that are being closed out.

Credit for Securing Particularly Desirable Business.

1. New customer who discounts bill.
2. New customer who pays within thirty days.
3. New customer who takes sixty days or over.

Half credit is given when the order is received by mail, one-quarter credit when the order is closed by the office.

Penalty for Loss of Customer, i.e., "Six months without buying."

Credit for Cooperating with Credit Department.

1. Information which results in saving account.
2. Local investigation of new account.
3. Valuable information regarding old account.
4. Penalty for bad debt through failure to report.
5. Penalty for bad debt not due to salesman.

Credit for Cooperating with Advertising Department.

1. Report on dealer advertising activities.
2. Getting dealer to use store advertising matter.
3. Getting dealer to use dealer electrotypes.
4. Securing mailing list from dealer.

Credit for Cooperating with Sales Department.

1. For every report turned in.
2. For calls made without sales.
3. Information of interest to other departments.

Penalties and Rewards for Quality of Salesmanship.

1. Misrepresenting facts.
2. Complaints from customers.
3. Goods returned "in addition to credit."
4. Falling off in sales over last year.

One large national concern in describing the point system says:

We need a measuring stick by means of which we can measure all territories and all men alike under varying conditions and in varying territories and still show the good salesman in proper comparison, whether he is in good or bad territory. We take the three largest considerations in the salesman's work, *viz.*: calls, orders, and volume, and after determining the approximate number of calls, orders, and volume in unit of retail sales which we expect to accomplish during the year, we fix on each of them a value in points to be credited to the salesman accomplishing one of the units of his job. For example:

	Points
For each call	5
Each retail order taken	15
Each unit sold retailers	1

Therefore, for each call a salesman makes he will be credited with five points, for each retail order taken (regardless of size), he will receive credit for fifteen points; and in addition, he will receive one point for each unit of sales.

We find by actual comparison with the range of calls, order and unit of sale, based upon the average experience in all territories over several years, that this valuation keeps the day's work balanced about in accordance with the importance of the work done. In territories where a large number of calls per day is possible, the orders run small; in sparse country, where few calls per day are possible, the orders run larger. A man working for distribution among the small trade would make a number of calls and take a large number of orders but the volume would be small. Another salesman in a country territory would only be able to make a small number of calls and take a few orders, but the country orders run larger and his volume would, therefore, average up his day's work.

Rating Plans. The rating plan aims to give ratings or classifications as to performance and to pay salesmen a bonus or give some recognition for this performance, on the basis that if a salesman can be helped to discover and overcome his weaknesses he will be a greater producer.

Men are rated according to the quality of their work each month.

A rating plan can be profitably used independently of the compensation plan to measure a salesman's effort, to point out weaknesses and to aid in the proper direction of effort. Salesmen should be encouraged to look ahead to a time when an inventory of their work will be presented.

Sales and Service Quota Plans of Compensation. This plan consists of:

1. A sales quota and a service quota.

This plan establishes a quota. Many quota plans are based on previous year's sales, population, business enterprises, etc. The service quota is the number of tasks that should be performed in relation to total calls.

2. A point system by which actual sales and service are translated into credit points.

3. A method by which the credit points (the work done) are translated into earnings.

4. A salary and expense allowance based on previous pay.

5. A plan for paying to the salesman the difference between his total credit points (actual sales and service performed) and the total debit points (money in salary and expense allowance advanced).

The Compensation Plan in Operation. The establishment of a salesman's compensation plan is a major proposition in marketing. Territorial assignments, changes in personnel, cancellation of orders, return of merchandise, and many other conditions make it necessary to define clearly how the compensation plan shall operate. Some of the problems which arise are:

1. How shall commissions be credited; upon the presentation of a signed order, or when the account is paid, or when in the case of exchanged goods the bill of lading on goods returned is received? By some concerns no commission is credited on a sale until full settlement is made in accordance with the terms on the order or returns received.

2. How shall special representatives be compensated? If a special representative assists a salesman in closing a sale, is the company entitled to a part of the commission on the sale, or shall it go entirely to the salesman? In some cases the company reserves a certain per cent of the commission.

3. How shall we compensate a salesman who finds on his territory goods from a territory controlled by another branch? If a sales representative finds goods in the hands of prospects that he has been working on within three months of the time they were purchased, the commission on such sales should go to him and not to the man who initiated the sale.

4. How shall provision be made for the return of goods or cancellation of sales just prior to the resignation of one man and the introduction of a new salesman on the territory? When the new salesman enters the territory and is able within three months to resell a customer who returned or cancelled goods, the commission on that sale should go to the original man who made the sale. Should the second sale be for products higher in price, the man effecting the higher-priced sale should receive the difference in commission between the high-priced and the lower-priced article.

5. When a salesman in one territory sells merchandise for shipment into another territory what is a fair division? The salesman initiating the sale should receive 25 per cent of the regular commission and the salesman in whose territory the goods are to be used should receive 75 per cent of the commission.

6. In selling syndicates, chain stores or a large company maintaining many offices, should the salesman on whose territory these various subdivisions appear receive any commission on a sale which was handled through a main office without his knowledge, or without his being a factor in the transaction? Opinion varies, but there should be a definitely understood policy.

7. What provision should be made as to the crediting of mail orders? Should the credit go to the salesman in whose territory the goods are used or not? Some organizations provide that in such cases if a salesman is able to show a record of a call during which he has solicited or demonstrated his products within a period of sixty or ninety days from the time of purchase, he is entitled to credit for the sale. This ruling often results in a stimulus for increasing the number of calls.

8. Who should receive the commission on the sale of products to a concern which after the purchase moves its place of business from one territory to another territory? Some companies give credit to the original person selling the goods, some give credit partly or wholly to the person into whose territory the purchaser moves, on the basis that the latter salesman must take care of the equipment and render service and on the ground that the original seller of the goods may have made the sale with the idea of getting the commission before the firm moved out of town.

9. If a buyer places an order with a salesman and then cancels because he wants to give the order to another man who has an adjacent territory what provision should be made? In such cases some companies split the commission, the man who originated the first order getting the larger commission.

10. When equipment is sold to concerns having an enterprise that moves about the country who should get the commission? It should be given to the man who brings in the order.

11. What is good policy when goods are sold on a rental basis? A certain rate of commission is allowed, payable only when the rental has been collected.

12. How should commissions be paid on partial payment sales? Some concerns wait for the final payment of the account, others pay 50 per cent when the first payment is made and the remaining 50 per cent when 50 per cent of the account is collected. Others pay a rate of commission as the installment payments are made. The point to watch is that there is not paid out in commission more cash than is taken from the user of the machine, because if at any time failure to comply with the contract occurs, the property must be repossessed and the purchaser usually forfeits what he has paid up to that time. An unscrupulous salesman, if paid full commission at the start, would make sales of this sort that were probably questionable.

13. How can the problem of paying commission be handled when other goods that are not the firm's own make are taken in exchange when a sale is made? Some concerns have a fixed allowance for the articles that are to be taken in exchange and after deducting one-half of that from the bill pay commission on the balance. Others deduct the entire amount and pay commission only on the cash returns.

14. When an article is sold to a firm already the owner of one or more of the same article, and within thirty days either before or after delivery of the new article one of their older units is shipped into another territory, what

policy should hold? Full discount or commission upon such sale should be given to the salesman into whose territory the unit is to be shipped.

15. When a company owning equipment moves one of its offices or any part thereof from one city to another and with it the equipment, should there be no transfer of credit for any sale? No.

16. How can an unexpected situation be provided for? The rule usually works satisfactorily that in any cases not covered by the special rules, involving interterritorial rights, the facts shall be submitted to the sales department, and the decision of the sales department shall be final.

COMPENSATION OF INDUSTRIAL SALESMEN

BY C. R. CARY, *Vice President in Charge of Sales, Leeds & Northrup Company*

The success which has followed the use of direct individual incentives has been so great, in so many different situations, that it requires some courage to discuss an incentive plan which is neither direct nor individual in the technical sense in which these terms are used when we discuss incentives.

It is only in recent years that serious study has been made of the subject of compensation for salesmen. A great variety of schemes has been proposed and doubtless used successfully. Without exception, all of these which have come to my attention have embodied, in one way or another, the effort to apply some form of a yardstick to the man's individual performance as a salesman and reward him in accordance with the results of this measurement. The plan which is described in this paper is based upon the premise that in industrial selling there are, alongside of services which may be quantitatively measured, other services which it is fatal to disregard, but which cannot possibly be quantitatively measured; it is the contention that in industrial selling it is to the advantage of all concerned to forego the advantages to be derived from a system which bases rewards only, or even mainly, on the results of the measurement of those elements of a man's service which may possibly be accurately measured, in favor of one which seeks to reward him on the basis of his total service to the company.

The term "industrial selling" may be defined as selling such industrial equipment as is normally carried on the books of the owner with a depreciation of 25 per cent per year or less. This would exclude consideration centering around those selling such articles as taps, dies, cutters, etc., which may be said to be consumed in the using. The reasons for emphasizing this limitation will become apparent later. The salesman's remuneration plan described has, without change, fulfilled its function admirably for an industrial sales group for a six-year period and we anticipate no changes in the future.

Two illustrations will serve to emphasize those services performed by an industrial equipment salesman, which cannot be measured. First, let us consider one extreme case—a man selling a simple, universally purchased, staple food product—like oatmeal—in a carefully limited territory, to a considerable number of grocery stores (excluding chain stores). His firm is selling the same product in neighboring territories, through similar men; all are governed by the same rules, are able to offer the same credit terms and ship from a common and adequate stock maintained in a nearby ware-

house; population records and food habits are well established. Under these circumstances it is difficult to visualize any influence, which that man's business activities may have for weal or woe to his employer, which will not be promptly reflected in his net sales curve or his expense account. Obviously, in this case, the thing to do is to relate the man's total income from his work to the results of his work—his sales.

Conditions of Industrial Selling. Contrast this with an equally extreme case illustrating the conditions under which all industrial selling in greater or less measure is performed. The salesman is handling a high-priced unit which has a long life expectancy; it is used for certain rather narrowly defined purposes and only the largest customers are in the market with anything even approximating regularity. The unit may be and should be altered at this or that point to adapt it to each customer's needs; it may need this or that addition to enable it to function to best advantage for the various applications. Not infrequently, in its less expensive forms it is more suitable for a given use than in a more expensive form. Even worse than this, there may easily be uses where the equipment in none of its forms should be sold, even though to a superficial observer any of them might appear suitable. The equipment is not carried in stock in finished form but is assembled, in part at least, after receipt of order in accordance with the specifications. If a mistake is made in the recommendations it may not become apparent for a long time after the event, and the responsibility has then become difficult to place. Under such circumstances a salesman may readily show a fine sales volume over a very considerable period before anything in that sales volume will give any clue to the fact that he is leaving behind him a trail of dissatisfied customers who will plague the organization for years to come.

Merely to refer to these conditions is quite sufficient to bring to mind the more important of the characteristics an industrial equipment salesman should constantly manifest but which may, in reality, be painfully lacking, without affecting his sales record for a long time.

Crediting the Sale to the Proper District. Looking at the subject from a very different angle, there is another ground for eliminating the individual incentive from the bonus system. The economic trend of the last ten years has rapidly increased the need for intensive team work within sales forces handling industrial equipment.

Previous to the World War, it was seldom that the industrial equipment salesman would not find, located within his territory, all the individuals whose approval was required before a purchase of equipment for a plant in his territory could be made. Now there are many lines and many markets in which most of the sales can be effected only after obtaining the approval of various executives, scattered perhaps between New York and California. The executive and staff in charge of production may be in the oil fields of Southern California, the engineering department in Chicago and the purchasing department in New York. All of these will have to approve of the purchase, yet one group may have greater weight than another and *a priori* no one can tell which. Obviously, it is seldom that the amount at stake is large enough to justify a salesman chasing back and forth across the continent, so the local salesman or representative in each district involved must be called upon to

take a hand. But the order, if received, comes from the purchasing agent even though, in the majority of cases, he has had to be given the least attention. However, in the case cited, the order was secured because the sales force in three districts each did its share, and who could appraise, with any accuracy, what each share was? If you cannot do this, you certainly cannot have a smoothly working system of salesman's remuneration based upon the orders received through him or from his district—it would not be fair to credit such an order solely to any one district, yet there is slim chance of making a split without injuring somebody's feelings. If the situation is further complicated by involving one or more distributing agents, instead of your own people, the case becomes positively hopeless. Parenthetically it may be added that because we see no hope in this direction, we are, with an important yet minor exception, eliminating local distributors from our scheme of distribution.

Now when an organization rewards its salesmen along purely individualistic lines, as for instance, through individual sales quotas, or sales contests of one type or another, it is only to be expected that each of those men will concentrate all of his energy upon building up his own total. He will at best give casual and indifferent attention to work which he might do for the good of the company but without effect upon his total. Also he will thoroughly resent being asked to share anything which he has the slightest ground to believe was obtained as the result of his labors.

To sum up the two reasons which led us away from any direct individual bonus: first, we expect services from the salesman, which could have but a remote influence upon his year's sales, and, second, it is more important to aim at perfect teamwork than at maximum individual performance.

So much for our grounds for sacrificing the undeniable stimulus given by a direct tie-in between a man's sales and his income.

The Leeds & Northrup Plan. The following is a brief outline of the details of the method of the Leeds & Northrup Company.

Our sales bonus, as well as our executive and subexecutive bonuses, is based upon the profits earned by the company. After all federal tax and dividend obligations are met, inclusive of a 6 per cent common dividend, the remaining profits are divided between the common stock and a main bonus fund. This main bonus fund is in turn divided into prearranged proportions for the executive, the subexecutive, and sales bonus funds. The sales bonus is in turn divided, also in accordance with prearranged percentage among the various members of the sales force. All of this proportioning is done at the beginning of the fiscal year. At that time, an estimate is prepared of the probable sales volume for the year, and on the basis of this estimate a budget of operations is prepared and an anticipated profit and loss statement as of the end of the year is drawn up. From this, after subtracting the anticipated dividend and tax requirements, the bonus fund is figured. After this total anticipated bonus fund has been determined it is subdivided by executive action into the three parts referred to above.

The sales department, because of the varied nature of our products, is organized into three divisions, each with its own sales manager. These three men, together with the advertising manager and the vice president in charge

of sales, review the performance of all sales and servicemen who have been in the organization two years or more, and apportion the anticipated amount among the various participants, each receiving an amount related to his relative importance to the company, as appraised by this group. In effect, this narrows down to a situation in which the amount each man receives is rigidly and mathematically proportioned to the taxable profits of the company, so that the information he receives as to the bonus he is to get takes the form of a straight line chart, one of the ordinates of which is taxable profits of the company and the other his bonus. Since the accounting system provides for a monthly profit and loss statement, this is used to give each bonus participant a statement, once a month, of indicated taxable profits figured for the year as based on the year-to-date figure, and from this he can see how his bonus prospects are developing.

No reference has been made to any tie-in between the sales record of the individual and the percentage allotted to him, nor is any present insofar as the current year is concerned. His sales record for the year is carefully examined, however, before the percentages which are to govern the distribution of the next year's bonus are apportioned. His record is then scanned, not only from the point of view of his success in bringing in orders, but also as to his performance in other directions—his judgment, cooperativeness, experience, technical skill, executive ability, length of service, etc., and the results of this examination are expressed, in effect, as a percentage of the sales bonus which is to be his at the next year's distribution.

Experience with the Plan. This particular method has been in use six years. There were twenty-six men involved at first; there were forty-nine in 1930. The executive management of our wage policy and profits distribution has been such that when taxable profits corresponded to a 12 per cent common dividend, the high-grade salesman would receive a bonus of about 50 per cent of his total salary for the year, while a junior salesman or senior serviceman would receive 10 per cent to 15 per cent of his salary. These figures of course vary widely, but are given as indicative of our interpretation of the general principle, that any financial incentive to be worthwhile must involve amounts which are worthwhile in the eyes of those upon whom it functions. Our experience (including a period with another but similar system) covers a period when the bonus to senior salesmen has ranged from zero during a depression to about 100 per cent of salary at the high tide of prosperity. While the salary roll is probably lower than it would be without the bonus plan, the salesmen unite with the company in the conclusion that from the financial as well as from other viewpoints the plan is highly satisfactory.

Basic Principles of the Plan. Certain principles embodied in this scheme have contributed materially to its success. The success of any incentive plan for industrial equipment salesmen will be materially affected by the degree to which these principles are embodied in it.

First and most important, *the arrangement, once made up, is perfectly understandable and also rigid for any one year*; no questions as to whether this, that, or the other, should go on his total, or whether favoritism is being shown in allocation of territories, or whether the factory is giving the square deal to each, come up. Human judgment and fallibility are, it is true, pres-

ent in the rating at the beginning of the year, but with these arguments once settled every one can tackle his job with a free mind; everyone knows that he cannot be "gypped" without gypping Uncle Sam's revenue inspectors. A large portion of the value of otherwise good incentive plans is weakened, if not entirely nullified, because of the argument and friction they engender between man and man, as well as between man and management. In fact, management is only too likely to overestimate the importance of the dollar stimulus and underestimate the importance of the braking power of argument and lack of confidence. Almost everybody prefers to work in peace, but let a salesman, or anybody else for that matter, get what he rightly, or wrongly, considers to be a raw deal, and thereafter he is only half a man on the job—one eye on his work and the other on making sure that he secures the fruits thereof.

Next in importance is *the invitation it extends to cooperativeness between man and man, district and district*. It places a premium upon enthusiastic distribution of newly acquired information or technique as widely as possible through departments. This effect is accelerated by judiciously spreading through the ranks the knowledge that service of this type scores heavily when future ratings are in the making.

The next point is that the plan *fosters a community of interest and reduces sources of friction between the salesmen and executives of all ranks*, with especial reference to those of the producing, engineering, and credit departments. In industrial selling there are, in normal course, only too many situations wherein the viewpoint of the outside men will lead them into direct opposition to the inside men who see those situations from a different angle. There is much to be gained, from an incentive plan in which the fortunes of both groups rise and fall together, and neither side can feel that the other is trying to secure a financial advantage. It was really surprising to note the immediate change in this respect which took place when this plan replaced one in which the salesman looked for their reward to an incentive plan related to their own efficiency, only, and the inside men to another and unrelated incentive plan. A most notable increase in efficiency in the overall operation of our organization, which could be attributed to no other cause than the introduction of this community of financial interest, immediately set in.

Finally, *the effect upon the man himself is important*. In industrial selling, we need more in salesmen than the ability to secure signatures "on the dotted line." Every high-grade organization selling to the industrial field expects to find in its salesmen, technical knowledge and engineering skill, diplomacy in guises unrelated to selling, judgment in bringing to light credit information, and, above all, restrained enthusiasm in the making of claims and promises. In short, we need really broad gauge business men on our sales staffs. The simple salary arrangement with no other incentive may be so used by a skillful management that it interprets clearly the ideals which the company has for its salesman, but even when so administered it leaves him an employee and nothing more. In spite of himself even the broadest-gauge man will remain colored by employee psychology. What is needed in industrial selling, as in no other type of selling, are men who are actuated by the owner motive, since out of sight and almost out of control of the manage-

ment they are constantly making decisions and taking actions which affect, in important ways, the future of the organization, even though those decisions and actions may not influence its present sales volume. Whatever the details of an incentive plan for industrial salesmen may be, the plan will lose much if it is not capable of definite and rigid interpretation and is not framed along lines which tend to give dignity to the man and to tap, not alone his sales instincts, but also all of his business instincts and abilities.

SUPERVISING SALES FORCES

BY JAMES L. PALMER, *Professor of Marketing, University of Chicago*

The term "supervision" does not have any generally accepted usage in sales management. It is construed by some executives to refer only to the actual overseeing of salesmen in the field. Others seem to feel that it is a term practically synonymous with management and includes such problems as selection and training. Other views range between these two extremes. One author may be quoted to the effect that, "supervision of salesmen consists of two great elements—field training and motivation." "Supervision, then becomes the process of discovering how nearly each salesman approaches the ideal or standard and of helping him to improve in those respects in which he is weak."¹ For present purposes supervision may be defined as the process by which deficiencies of salesmen are detected and men are induced through motivation and training to do the best possible job. Thus it involves: (1) analysis of performance; (2) the application of corrective or improvement measures. Too much emphasis cannot be placed upon this dual aspect of supervision. It is the feeling of some observers that corrective measures are often applied prior to any adequate analysis of performance. This is usually due to a failure either to maintain adequate sales records or to organize properly for supervision in the field.

Now if the above definition of supervision be accepted, it is obvious that supervision is not entirely a matter of work in the field. Motivation of salesmen may come from personal contact with supervisors or other executives in the field, from a compensation or contest plan devised and administered by the home office, from conventions or conferences held either in the field or at the home office, or through printed material prepared usually at headquarters. Similarly, senior salesmen may undergo training either in the field, at the home office by attending schools, conventions, or conferences, or through the medium of printed material. Salesmen's performance may be analyzed either by observation of men in the field or through maintenance of records. The basic problem of supervision confronting every sales executive is that of selecting such a combination of the above methods and devices as will produce the best results. It is thus expedient to consider supervision not as an isolated process of practicing foremanship in the field but as a much broader process involving the use of various devices, only one of which is field foremanship.

¹ KENAGY AND YOAKUM, "The Selection and Training of Salesmen," pp. 319-320, McGraw-Hill Book Company, Inc., 1925.

The *central problem of supervision* is that of getting salesmen to perform their various tasks with maximum efficiency. This problem may be broken down into a large number of specific problems which serve to define the task of supervision with precision. Typical problems of supervision are those of getting salesmen:

1. To sell the full line of products.
2. To distribute their efforts in proper proportion over the line of products.
3. To devote proper attention to new products.
4. To distribute their efforts properly over their various customers and prospects.
5. To keep old accounts active and at the same time secure a satisfactory number of new accounts.
6. To sell every customer as large a part of his total requirements as possible.
7. To make full and intelligent use of their time.
8. To plan work effectively.
9. To present their propositions effectively.
10. To keep their expenses at a minimum.

This list of problems is in no sense exhaustive but is suggestive of the objectives at which supervision must aim.

Such problems as those enumerated above cannot be solved nor can any industrial sales organization be brought under control unless salesmen are carefully selected and thoroughly trained; unless effective incentives are brought to bear upon the sales force; unless performance standards are established; unless the working plans and methods of salesmen are specified in advance; unless salesmen's work is methodically subjected to periodic inspection; and unless their work is carefully appraised through the use of records which reveal every significant fact about it. The omission of any one of these activities weakens any plan of control; if each is effectively developed in the management of a field selling organization it will have been brought under as close a control as can be achieved.

The most important control devices which the sales manager may employ are incentive plans, quotas and work schedules, field supervision, and records and reports. Each of these has its place in the management of field selling organizations and the importance of each varies with circumstances.

Control by Incentive Plans. Incentives are extremely important in most sales organizations because of the difficulty of getting work done properly by other means. They are applied through compensation plans and contests on the one hand and personal inspiration on the other.

Such incentive plans as commission or bonus methods of wage payment, while often extremely valuable in selling, cannot be depended upon completely to solve the control problem. There are many reasons for this, among which the following are important:

1. Incentive plans as a rule are aimed at the quantitative aspect of sales performance—at volume. Hence they have only an indirect effect upon quality and method of work. They may in fact impair quality, as when a commission plan encourages overselling or results in cream-skimming.

2. The task of the average salesman is so many-sided that it is often impossible to devise a system of incentives which will properly direct his efforts

3. Certain incentive devices, such as conventions and "pep" letters, seem to have been overdone and hence have lost much of their incentive value.

4. Many salesmen seem to be more or less indifferent to incentives and do not work harder as a result of their use.

5. Very little is known about the value of different types of incentives, and the motives which inspire salesmen. The development of incentive plans in sales work is at present largely a matter of continuous experimentation or trial and error.

The above shortcomings of incentive plans are not presented with any intention of belittling the value of such plans. In most companies they are without question very useful in directing salesmen. The extent to which they are used and the importance attached to them should be contingent, however, upon the characteristics of the individual sales job and the availability of other methods of control.

The problem of devising a compensation plan which will effectively stimulate salesmen, direct their energies into the desired channels and do justice to all parties, is in most organizations a very involved one. It requires careful consideration of many factors and conditions, and cannot be handled as a matter of ordinary routine. Many concerns have not had occasion to study their compensation problems thoroughly and as a result are using simple and crude methods of compensation which do not realize fully upon the control possibilities of compensation. Exhaustive analysis of the objectives of the salesman and the conditions under which he works will reveal whether or not incentive plans of compensation can be advantageously used in controlling him or in directing his efforts.

The simplest forms of remuneration are straight salary and straight commission. As a rule neither is an entirely satisfactory method of compensation yet both are fairly extensively used, presumably because they can be simply administered and because they avoid some of the entanglements which often result from the use of more complicated plans.

The *straight commission plan* seems to give best results under the following circumstances:

1. When the product is hard to sell and a powerful incentive is needed to keep the salesmen pushing ahead.

2. When most of the emphasis in the salesman's job is upon sales volume alone.

3. When there is little danger of overselling the customer.

4. When the customer does not repeat his purchases, except at infrequent intervals.

5. When the company's selling job is of such a nature that close control over the salesman cannot be exercised.

6. When there is relatively little danger of the practice of splitting commissions becoming prevalent.

7. When sales volume is fairly regular from season to season and through the various stages of the business cycle.

8. When variations in sales volume are largely within the salesman's control.

The assumption underlying the straight commission plan of payment is that the best way to get a man to work hard is to base his remuneration

directly upon his accomplishment so that he knows that every time he closes a sale a specific amount will be added to his income. The assumption is probably sound. The more direct the incentive—and the more objective in character—the greater its force. Despite its incentive value *the straight commission plan does not, however, perfectly serve the needs of the majority of industrial sales organizations.* There are numerous reasons for this, among them the following:

1. Industrial salesmen frequently are called upon to engage in work that does not directly produce volume, for example, the servicing of customers. Salesmen cannot be induced to carry on this work properly when paid on a commission basis because of their feeling that direct selling effort alone produces income.

2. Industrial sales fluctuate rather severely from one period to another, resulting in both excessively high and unreasonably low levels of compensation.

3. The average industrial sales organization sells numerous products and to various classes of trade. It therefore wishes to follow a selective selling plan, concentrating upon certain items and trade groups, whereas under a straight commission plan the salesmen simply follow the line of least resistance. The result is often large volume on unprofitable items and small volume on high-profit items.

4. In many industrial sales organizations there are very extreme variations in the size of individual orders. As a consequence the commission plan produces exceptionally wide variations in the income of the salesmen.

5. Factors beyond the salesman's control probably have a greater effect on volume in industrial selling than in the selling of consumers' goods.

6. In many organizations the efforts of several salesmen are brought to bear upon a single prospect, thus making it difficult equitably to reward each man.

7. In organizations in which the salesman does missionary work with the ultimate buyer, orders being filled through an agent or supply house, it is difficult to establish a base for the calculation of commissions.

Space does not permit a thorough consideration of the question as to how these various difficulties may be met in formulating a compensation plan, but a few brief comments will perhaps suggest possibilities.

A large concern selling heating equipment which has an unusually involved problem, instead of paying commissions on the volume of each salesman, pays each man a base salary plus a substantial monthly bonus. The total bonus to be distributed among the salesmen of a branch is a predetermined percentage of branch sales. A rating scale is used in calculating the bonus earned by each man. Each salesman is rated on sales performance on each product line and on various factors other than sales performance, such as adequacy of trade contact. The ratio between the total number of points earned by a salesman and the total earned by all salesmen in his branch determines the share of the total bonus to which he is entitled. It will be observed that the plan serves not only to motivate salesmen but also directs their efforts into desired channels. It emphasizes something besides total volume.

The problem of handling a situation in which sales fluctuate widely from one period to another is often solved either by paying a base salary plus a small commission rate on total sales or by paying a base salary plus a sub-

stantial commission paid only on sales in excess of quota. Either plan provides a relatively weak incentive but is probably to be preferred to no incentive at all.

The regularizing of salesmen's incomes in an organization in which individual orders vary widely in size may be effected by paying a base salary plus a substantial rate of commission upon sales in excess of quota, calculating monthly sales by means of a six- or twelve-month moving average, rather than by taking the actual sales of any one month.

The problem of compensating salesmen who work with ultimate buyers but whose orders are filled through jobbers or supply houses is very difficult to solve satisfactorily. The results of their efforts cannot be isolated. A solution which is fairly effective is sometimes found in a point system of compensation, in which point awards are based upon the various aspects of the job. Among the factors which may be rated are volume of orders turned over to supply houses and total company sales to individual supply houses. This problem is so involved, however, and arises in so many different circumstances that it is impossible to generalize concerning it. One company has solved it by the simple expedient of paying its men on a straight salary basis.

Expense Control through Compensation Plans. Occasionally in selling, compensation plans are used for the purpose of expense control. Thus in one organization a standard selling expense ratio is set for each salesman and a monthly bonus is paid if the actual ratio falls below the standard. A salesman whose standard is 5 per cent, who sells \$10,000 and incurs expenses of \$400, receives a bonus equal to a predetermined percentage of the difference between \$400 and \$500. In the average sales organization such a plan could not be used to advantage as the sole basis upon which to award bonuses or commissions, but it can often be used profitably as part of a broader plan of compensation.

One should call attention to the possibility of introducing variations into the straight commission form of wage payment. A great many organizations seem to be satisfied to use the basic plan without frills, yet it is often possible to introduce variations to good advantage. Take, for example, a company which sets sales quotas and expects each salesman to reach and if possible surpass his quota. The straight commission plan gives no assurance that the quota will be either reached or surpassed. But if the salesman is paid, say, 5 per cent on total sales in event of failure to reach quota, $5\frac{1}{2}$ per cent of total sales if he reaches quota, 6 per cent of total sales if he reaches 110 per cent of quota, etc., he is pretty apt to put forth as much energy as possible not only to reach but to exceed quota. The greater the volume the greater the incentive to push ahead. It may be objected that such a plan as this produces an increase in selling cost as volume increases but this is not necessarily true. The plan can be so set up that selling cost ratios decline as volume increases.

Many variations in practice are introduced into incentive plans in selling. The subject is a fascinating one but very broad and complex. The sales executive who will search far enough, give the matter sufficiently close study, and if necessary call upon expert counsel, will find in financial incentive plans an effective device for improving the performance of his salesmen. Careful

attention to the possibilities of compensation plans is of course especially important in organizations in which other methods of control cannot be successfully employed.

Control through Standards and Work Plans. As a further means of solving his supervisory or control problem the executive may rely upon operating standards and work plans. The first step in any control plan is to instruct the worker as to what is expected of him. In practice this usually means giving him a sales quota. The objection may at once be raised by some executives that accurate quotas cannot be set for individual salesmen. This we may concede without argument in many cases. Yet unless a salesman is assigned, at the beginning of each period, a definite responsibility of some sort, unless there is a definite understanding as to work to be done, control is out of the question. Management must then rely largely upon the opinion of the salesman as to quality of actual performance. Uncertainty as to the future argues, except in extreme cases, for flexibility of quotas rather than for their abandonment. It also argues for restricted use in the sense that they should not be employed, for example, as a basis for compensation if they cannot be set with reasonable assurance of accuracy.

In some respects the setting of accurate quotas is easier in *industrial* selling than in the selling of most consumers' goods; in others it is more difficult. It is easier in that the market for most industrial goods consists of a definite, determinable and relatively small number of buyers. Thus a manufacturer of drive chain knows that his prospects consist of all industrial establishments which transmit power. If he can secure a list of such establishments he has an excellent basis upon which to attack his problem, and in this respect is in a stronger position than, say, a manufacturer of radio sets who cannot determine exactly how many buyers there are in a given territory. On the other hand the manufacturer of drive chain will experience real difficulty in determining the amount of business which should be obtained in a certain period from an individual prospect, or from all the prospects in a certain territory. He may project past sales into the future, a useful though highly questionable procedure. Or he may succeed in establishing an index of sales potential by discovering relationships between drive chain sales and such factors as number of employees, horsepower, etc.

The logical procedure in establishing sales quotas is to employ not only past sales data but also thorough analysis of territory potentials. This requires a reasonably complete list or count of the number of potential buyers in each territory, estimates of the probable total purchases of each buyer, and estimates of the percentage of each buyer's business which the company may reasonably expect to secure. Past sales data are of course useful in making these latter estimates. But to fail to analyze each territory, by accounts if practicable, or to set quotas solely upon the basis of past sales is to perpetuate many situations in which unsatisfactory market coverage is being secured. In nearly any company an analysis of a typical sales territory will reveal numerous sources of business which may profitably be exploited, but which are never sought out in the absence of such analysis. Any executive who questions this statement should make a test analysis of one of his own best territories.

It is not contended, of course, that even the most exhaustive of market analyses will entirely eliminate errors in setting quotas. There are unpredictable factors in selling. Some of these cannot be removed by any known technique of forecasting. Detailed analysis will reduce error, however, and will uncover many specific situations to which attention can profitably be given.

It is advisable from a control standpoint to establish salesmen's quotas not only in total, but also by product groups and by trade groups or individual customers. The probability of discrepancy between quotas and performance is of course increased by such a procedure but it serves very effectively to direct salesmen's energies into desired channels.

It is advisable, when possible, to set quotas in physical units in order to eliminate any discrepancy which might be caused by price change. Two companies with which I have come in contact solve this problem by giving each product a certain weight in points, thus setting quotas in terms of points. This is obviously not necessary when a company is selling only a single commodity.

A problem which looms large in quota setting is that which results from wide variations in the size of individual orders. An adding machine salesman may fail to sell a single machine for three months, and in the fourth month secure a single contract running into tens of thousands of dollars. This situation is fairly common in industrial selling, though it is not usually found in so extreme a form as the above illustration would suggest. In such cases it may be possible to establish fairly accurate quotas over a six- or twelve-month period, but impossible to anticipate how much business a salesman will obtain in any one month. If, as is usually the case, it is desired to set monthly quotas this may be done by employing the statistical device known as the moving average. An illustration will serve to show how this might work out. Suppose the monthly volume of a salesman in the first six months of 1929 were as follows and that these same figures were to be used as 1930 quotas:

January	February	March	April	May	June
\$6,000	\$4,000	\$10,000	\$5,000	\$8,000	\$3,000

Total sales for the six-month period were \$36,000, a monthly average of \$6,000. In setting the quota for June this figure would be used instead of the actual sales figure, \$3,000. Let us assume now that actual sales in the first six months of 1930 were as follows:

January	February	March	April	May	June
\$5,000	\$7,000	\$9,000	\$2,000	\$10,000	\$5,000

It will be observed that there are wide discrepancies between the 1929 and 1930 monthly figures, and that if the former were used as 1930 quotas results would be very unsatisfactory. But the average of the 1930 monthly figures is \$6,333, which under this plan we should use as the June sales figure, as compared with \$6,000, the quota for June.

In setting the July quota the same procedure would be employed except that averages would be taken of the February to July figures, dropping January and adding July. Thus in the above illustration if July, 1929 sales

were \$9,000, total sales for the six-month period would have been \$39,000, an average of \$6,500, the quota for July, 1930. If sales in the latter month were actually \$7,000, the total for the six-month period in 1930 would be \$40,000, an average of \$6,667. This figure would be used as actual sales for July. The discrepancy between \$6,500 and \$6,667 is of course much less than that between \$9,000 and \$7,000, the two actual sales figures for July. For the remaining months of the year the procedure is simply continued.

The plan may appear complicated, but actually it is extremely simple. It irons out sharp fluctuations in month-to-month sales and is perfectly fair to the salesman. It may be operated on a three-, six-, or 12-months base to suit the needs of the individual organization. It is being used effectively by at least one company and has fairly wide application in industrial selling. It will not solve the problem, however, when sales fluctuations are extraordinarily violent.

Total sales volume is of course not the only standard of performance by which a salesman should be judged. Further discussion of this problem will be deferred, however, to a later point.

Detailed Operating Plans. When circumstances permit—and this is oftener than commonly supposed—sales quotas should be supported by work plans or schedules, the purpose of which is to provide salesmen with detailed operating plans and specific objectives. It is desirable for the salesman to know at the beginning of each period not only how much he is expected to sell but when, how, and where he is going to sell it. It is customary in selling to use route sheets but quite frequently these sheets serve merely as a salesman's itinerary. Under favorable circumstances they can very readily be expanded into control devices of real importance. Contemplate for a moment, for example, the advantages of a route sheet showing not only the towns in which the salesman is to be on each day of the month, but also the names of the customers and prospects to be called upon, the specific objectives to be realized on each call and the business to be secured from each buyer. Objection will at once be raised that it is impossible to plan the work of salesmen in such detail, that the behavior of individual buyers cannot be forecast and that too many unexpected developments are constantly taking place to make any detailed working plan practicable. These objections in individual cases may be perfectly valid, though there is ground for the belief that it is a rare sales organization which cannot advantageously make some use of detailed work plans. Their precise character, the length of time they cover, the amount of detail incorporated in them and their flexibility will depend upon the individual case, but some sort of plan can be formed to fit every situation.

The question usually arises as to whether working plans should be drafted by the salesman or by an executive. This cannot be answered categorically except to say that both parties should participate, and management should carefully scrutinize and approve final plans. Usually considerable latitude should be given the salesman. On the other hand if the central sales office or branch is well organized it will usually possess some information to which the salesman does not have access and which may affect his plan of action. On matters of territory management the judgment of the man in the field

cannot as a rule be relied upon fully; hence the importance of a careful review of working plans by an executive.

The practice of classifying accounts by *desired frequency of call* is another control device. Even when detailed work plans are not employed this device may be helpful in securing proper territory coverage. In most sales organizations customers and prospects may be divided into A, B, C, and D groupings, and standard frequencies of call may be established for each grouping. If records of actual calls made are properly tabulated and studied it is then possible to keep a close check upon the work of salesmen in contacting individual accounts.

Whether an organization merely establishes standard frequencies of call for its customers or whether it employs detailed work schedules the importance of concrete plans of some sort in selling work cannot be overemphasized. Hit-or-miss territory coverage will not give control. While it is perfectly true that planning is often difficult in sales work it can always be done in some degree. It is probably easier in the selling of raw materials, supplies and parts than in the selling of equipment. Whatever be the character of the individual sales organization, and however unpredictable be its sales situations it can do a certain amount of planning in managing salesmen. If these men are allowed to run their own courses and move from one situation to another as obvious needs or opportunities appear profit opportunities will be lost.

Control through Field Supervision. Another important control device is field supervision. The term is a distasteful one in many organizations and to many salesmen. Executives sometimes prefer to delegate practically all responsibilities to salesmen—"making them sales managers in their respective territories"—and salesmen quite generally resent being supervised. Having fully in mind the fact that there is often much to be said in support of these viewpoints there are nevertheless three distinct control functions which cannot be performed except through supervision in the field. These are: (1) inspection of the method of work of salesmen, (2) corrective instruction on the job, (3) motivation through personal contact on the job. The importance of these three functions can hardly be questioned.

Organization for field supervision of course varies widely from case to case. In industrial selling a high degree of specialization is usually out of the question, as the average organization probably does not employ over one hundred salesmen and the number is frequently much less than this. As a rule salesmen report either to a branch manager or to a home office executive. Branch managers and home office executives usually have many duties to perform other than those relating to personnel. Sales organizations selling to the retail trade and numbering several hundred salesmen quite frequently employ specialized supervisors whose major responsibility is that of periodic contact with men on the job. These men usually report to branch managers. Except in unusually large sales organizations such a practice seems inexpedient. Salesmen are relatively few in number and far apart, as a result of which the cost of maintaining a set of supervisors is apt to be very high.

Noting that a few large organizations may be exceptions, we may proceed on the assumption that the task of supervision must be handled either

by a branch or home office executive with a wide range of duties to perform. In such a case the most important supervisory problem is to induce the executive involved to devote proper attention to men in the field. In most organizations this is a real problem for several distinct reasons, among them the following:

1. The typical executive carries a heavy load and more or less out of necessity is prone to give his attention to routine matters which must be handled, and neglect matters which are not urgent and do not press in upon his attention.

2. Frequently executives do not regard field contact for development and motivation as a task of major importance.

3. In many instances executives do not regard themselves primarily as personnel executives. They seem to proceed on the theory that the best way to develop salesmen is to turn them loose, let them alone and hold them responsible for results.

4. Executives with varied responsibilities frequently have no special skill in the arts of training and motivation. They lack either the time or inclination to study personnel problems sufficiently intensively to develop effective techniques for solving them.

There are several possible solutions for this problem. If general management has the right point of view and sees to it that men in charge of salesmen are trained in this same point of view most of the conditions above enumerated may be removed. Overloading of branch executives may be prevented by providing office assistants to handle detail. Emphasis can be placed upon the importance of developing man power. After all, the capable executive is not the man who performs his own routine responsibilities well but rather the man who projects his personality throughout his organization, thus enabling many individuals to improve the quality of their work by application of the knowledge and skill which he has acquired. The effective sales organization is not the one with a brilliant salesman at its head; it is rather the one which is directed by a capable builder of salesmen. These may be platitudes but the fact remains that one may very easily find ample evidence to support the statement that in sales work there is a widespread tendency to neglect problems of personnel. It is not urged that every sales organization have a personnel manager. This unfortunately does not solve the problem. The main responsibility for solving the personnel problem must inevitably rest with that group of executives who come in personal contact with salesmen. No plan of training or motivation can be made effective unless they are capable personnel managers.

Let me cite two cases of sales supervision which lie at opposite extremes. In one company with which I have come in contact new men are taken into the sales organization, given a smattering of information about the product and the trade, and are assigned a territory. Their subsequent contact with executives is confined to occasional visits to the home office. Rarely does an executive go into the field. The salesman works alone and is expected to produce results. In a second organization new men are given a thorough training before being assigned a territory. They are visited at approximately monthly intervals by a supervisor whose function it is to observe the quality of their

work and suggest improvements in method. The company has made elaborate difficulty analyses of the job of the salesman and of that of the supervisor. The salesman is thoroughly trained in meeting difficulties encountered in selling; the supervisor is shown concretely how to handle any ordinary supervisory problems which he encounters. Each supervisor is responsible for the performance of between five and fifteen salesmen, and spends nearly all of his time on supervisory work. His is not a desk job. This latter organization is generally regarded as one of the most effective sales organizations in this country. The former is held in no particular esteem anywhere, and the company happens to have been losing money steadily for years.

It does not follow, of course, that every sales organization should have a specialized supervisor for every five salesmen. It does seem to be true, however, that the aggressive, hard working, well informed salesman who is fully supported by an alert management gets the business. If a sales force is so small or so scattered over the country as to preclude the use of specialized supervisors the problem is simply so to train branch executives or even the sales manager, and so to arrange their work that they can and will develop skill in and devote much of their time to the single problem of developing men. I have heard a purchasing agent of wide reputation assert repeatedly that nine salesmen out of ten who call on him do not know as much about their business as he does. These men are industrial salesmen. Are industrial sales managers aware of this condition, and if so what are they doing about it? Are company presidents and general managers aware of it, and if so what are they doing in the way of giving sales executives such assistance as they must have in order to solve this problem?

Control through Performance Records. The final step in the process of controlling salesmen involves analysis of performance through records of activity. This subject is a very broad one and time does not permit an exhaustive discussion of it. The facts needed periodically for the control of salesmen vary widely from case to case and depend in the individual company upon the nature of the sales job. Among the types of data which may be profitably gathered in many sales organizations are the following:

1. Sales in total, and by product groups and trade groups, with comparisons between salesmen.
2. Average number of calls made by salesmen, with comparisons between salesmen, and with each man's sales volume.
3. Number of calls, number of sales and sales volume by days of week.
4. Average number of hours per day spent in presence of customers and prospects, with comparisons between salesmen.
5. Number of new accounts obtained and volume of new business done in each period.
6. Customer mortality—volume of old business and number of old accounts lost in each period, with reasons.
7. Detailed analysis of the purchases of each major customer over a period of time.
8. Average sales volume per account compared with potential, when determinable.
9. Selling cost ratio compared with standard, with controllable and uncontrollable expenses separated.

10. Per cent distribution obtained by each salesman in each class of trade.
11. Data on salesmen's progress in handling individual accounts, showing number of calls, results thereof, sale of new items, etc.
12. Comparison of number of calls, number of presentations, number of demonstrations, number of trial orders, etc.
13. Analysis of repeat business, useful in reflecting the salesman's skill in servicing or retaining customer goodwill.
14. Cost data showing cost to sell different classes of business and if possible net profit realized thereon.

The above list is not exhaustive nor are all of these items of information useful in every organization. As I have previously stated the facts of each case determine the value of different kinds of information. It is desirable in most organizations, however, to take such a list as the above, preferably a more complete one, and check through it to see whether all facts of value in controlling salesmen are actually being obtained and utilized. Facts of course cost money and no end of expense can be incurred in securing them. Statistical and accounting analysis can be very easily overdone. This is not to be encouraged, of course, but the periodic tabulation of basic data that pay their way by strengthening the judgment of executives is an indispensable part of any system of control.

Summary. I have attempted to outline the basic elements of control in the management of salesmen. They appear to me to be motivation, performance standards, working plans, field supervision, and accounting and statistical analysis. All are important, though in varying degrees in different situations. I am of course well aware of the fact that much of what I have said is of a controversial nature, that my suggestions are in some cases not easily reconciled with certain prevailing philosophies of management. I have proceeded, however, on the assumption that control over field operations is desired, that management can more effectively direct certain aspects of sales work than can salesmen. It is probable that the assumption is justified in most sales organizations, but an exception may occasionally be found.

HOLDING SALES CONFERENCES

By C. T. ANDERSON, *Sales Manager, The Oliver Ditson Company*

Are sales conferences worth while?

Do they repay the labor and expense involved?

Which is better—a series of small conventions in different parts of the country or the big, national, "hippodrome" performance?

These are some of the questions which confront sales managers. They are real problems for the concern that has never held sales conferences, or that has held them unsuccessfully. Sales conferences can be productive of increased sales, enthusiasm and loyalty, or they can be costly fizzes. Firms which hold successful sales conferences regard them as desirable and necessary. The others try to forget them and resolve never again to attempt the undertaking.

Sales conferences may be divided into two classes, first, the big national convention at which the entire selling organization is brought to a central

point and, second, the zone convention at which the entire selling organization is gathered at strategic points in various parts of the country. Both types have their advantages, but this is about all that they have in common. They require different handling and cannot be expected to accomplish the same results with equal effectiveness.

Advantages of the Big National Convention. 1. The national convention gets together all the men of the selling organization, enabling them to become acquainted with one another, with the officers of the company and the department heads at the home office. Men new in the organization meet the old-timers. All present become acquainted with the headliners in the sales organization, whose names have been featured in letters, bulletins and house magazines.

2. A large convention cultivates *esprit de corps*—the men see that they are members of a large family. They establish contacts and relationships which increase their interest in the business and bind them to it.

Men coming in contact with officers and department heads are enabled to iron out petty misunderstandings and difficulties about which they have been corresponding. It is often amusing to see how some salesmen build up in their minds an utterly wrong conception of the type of individuals there are at the home office. Very often a few minutes' conversation, a hand clasp and an expression of goodwill is enough to entirely wipe out misconceptions of long standing.

3. Men can be conducted through the factory and offices, to see how the goods are manufactured and how the various departments function. They see how the factory is slaving to keep production up to sales. Their attention is called to the numerous and rigid inspections designed to make their work as salesmen easier. When they are conducted through the various departments of the office they begin to have an appreciation of the difficulties under which department heads labor. They see that the credit manager is not a devil with cloven hoofs and horns on his head, but a real human being who is trying to do his best to get in money and still accommodate customers.

4. A convention at headquarters enables men to see tests, demonstrations and displays of the product which often it is not possible to stage elsewhere. They can ask questions and get information on raw materials, construction and performance which it is difficult to give by mail.

5. A large convention engenders enthusiasm. Its mere size and mass is impressive. Men are impressed with the fact that the company is doing a business of national, or even international scope. They are proud to belong to such a large organization. A large audience is an inspiration to a good speaker and inspirational talks given before a large meeting generally have more fire and ring than those delivered before smaller groups.

Disadvantages of the Big Convention. 1. The big convention takes all the effective men from the field at the same time, with the result that sales drop. Not only do they drop for the period of the convention, but for several days before and several days after. Despite the urge of the sales managers that each man coming to the convention bring with him a bunch of orders, the excitement of anticipation and the necessary preparations for leaving generally interfere seriously with sales for several days before the men leave the territory. On their return they find an accumulation of office matters, service calls and other unproductive work which keeps them from selling. This is saying nothing about the period some men seem to need to get back into the harness and recover from the effects of the convention.

A week's convention at a central point in the United States can easily kill two-thirds of a month. This is especially true if a number of the men come from far distant points such as the Pacific Coast, Canada, Southern Texas, Florida, etc.

2. The expense of a big national convention is very heavy: railroad fares to and from distant points, brass bands, banquets, special decorations, and a host of small items mount to a staggering total.

3. A big convention held at the home office generally interferes seriously with the work and operation of the home office departments. Salesmen are apt to feel that just because they are on a vacation and have nothing to do, therefore the department heads have unlimited time on their hands with which to visit the salesmen, answer their questions and entertain them.

4. It is difficult to put across an educational program at a large convention attended by several hundred men. A certain amount of generalization is necessary so that the remarks made will apply to all sections of the country, and the various types of individuals.

Unless great care is exercised it will not be possible for all men in the hall to see the charts on the platform, demonstrations that may be made or to hear the speakers. The result is that the men on the edges of the crowd soon lose their interest and begin to talk among themselves or go to sleep.

5. At a large convention it is very seldom that time can be allowed for questions or discussions. The result is, one never knows how well certain talks are going across, or how many men are leaving the convention with only a hazy understanding of the subjects on the program.

Advantages of the Small Convention. The small convention, whether held at the main office or in various cities convenient to men in surrounding territories, differs in more than size from the large convention, and therefore requires different planning and technique of handling. Some of the advantages of the small convention, or conference are as follows:

1. Generally a series of small conventions can be held at less expense than a large one. This is due to the saving in railway fares and big entertainment features.

2. A local or zone convention can be held in two days time, whereas it is seldom considered worthwhile to bring all the men in to a big national convention for much less than a week.

3. At a small convention of twenty-five or fifty men all the boys become acquainted with one another and the presiding officer has an opportunity to shake all of them by the hand and even have personal conferences with a large number of them—things that are hardly possible at a national convention even when plans are made to meet all the men present.

4. Perhaps the greatest advantage of the small conference is that it enables excellent educational work to be done. When held in various parts of the country it is possible to make a local territorial application which must be omitted in a national convention. Time can be arranged for questions and answers. Men feel more free to ask questions and to reveal their ignorance in a small conference than they would before a large crowd.

Disadvantages of the Small Convention. It is oftentimes difficult to get up a rousing convention spirit in a small group of men. This is especially true if the conference is held in a district office with which most of the men are familiar and if there is not some officer from the home office to lend a glamour

to the occasion. The meeting has not the novelty of a convention at a far distant point and there is absent the natural enthusiasm which is created by a big mob having a good time.

Men like to get acquainted with the home office folks. They want to see the people with whom they correspond and like to form personal contact that they may get inspiration and information which it is difficult to convey by any other means.

Many men regard a national convention as a vacation. They are glad of an opportunity to take a trip out of their territory at the company's expense and are disappointed if national conventions are not held about every so often. It is also true that many men, especially those working on a commission basis, do not like to see national conventions held too frequently because it means a decrease in their earnings during the time they are away from their offices.

The Secret of Successful Sales Conferences. As in most undertakings, careful planning and efficient management spell the difference between success and failure. In few business undertakings do these two principles yield greater rewards when observed and greater disappointment and trouble when disregarded.

Some of the important things to plan for are as follows:

1. Why should the conference or conferences be held? What are the objects to be accomplished? What are the principal messages which the firm wishes to deliver? Conferences should not be called simply because, according to tradition, it is time to hold one. The men who attend conferences will never think any more of them than the management and if the management is not thoroughly sold that a conference is vitally important and necessary, the men will be quick to detect the absence of motive.
2. How can the objectives best be reached—by means of a large convention or a series of small conferences? If the purpose of the convention is to celebrate a successful year, to honor leaders in the organization, to show men an addition to the plant or to bind together a sales organization that shows rifts, then obviously, a big convention at a central point is the thing. If, on the other hand, intensive educational work has to be done; if local territorial problems have to be solved; and if close personal contact is desirable, then the small conferences in various cities would probably be better.
3. Just what, specifically, are the subjects (with their subheads) that are to make up the program, and who are the best persons to talk on them?
4. What is the best arrangement of the talks to secure climax and avoid anticlimax? What arrangement seems logical so that the program will grow in interest as it progresses and the subjects will follow one another in some sort of order?
5. What is the best time to hold the conference or conferences, in view of expected sales volume for certain months or seasons, approaching sales contests or holidays? Perhaps nothing will so alienate the affections of salesmen's wives as to bring their husbands into a conference over Thanksgiving or to force them to leave their homes on Christmas Eve.
6. What is needed in the way of models, displays, decorations, signs, literature, hotel accommodations, entertainment and the multitude of other details which, though small, are of vital importance to the successful running of a convention.

These questions should not only be asked and answered, but should be made a matter of record. Duties should be delegated to those competent to discharge them and the whole convention arrangements should be placed in charge of one man whose word is law. Everything must be planned in advance and then the plan adhered to and worked. Conventions which are only half planned are sure to be disappointing. The sales manager who expects to fill up half his program somehow, by means of delays or unforeseen events or inspiration of the moment, is headed for disaster.

Hints on Writing the Program. Every minute of the entire convention period should be accounted for. The program should state when the convention begins, the duration of the talks, the time and duration of recesses and luncheon periods, as well as the names and titles of the speakers.

It is a moot question whether convention programs should be distributed to the men attending or whether announcements should simply be made from the platform. Some say that the distribution of the programs shows the men its plan and purpose, thereby stimulating enthusiasm and eliminating the asking of countless questions as to the plans for the convention. Others contend that better attention and attendance is secured if the men are in doubt as to what the next subject will be. Some men are inclined to absent themselves during the delivery of certain talks with the subject of which they feel thoroughly familiar.

The best programs are not necessarily those in which the speakers are all officers of the company or men of national repute. The guiding principle in selecting speakers should be to pick out men who can speak with knowledge, earnestness, conviction and enthusiasm on the subjects assigned to them. They should be men whose delivery is good and who can talk from notes instead of having to read from a manuscript. Some men can read very interestingly from manuscript but others do so in a dull, droning voice which acts as an effective sleeping potion.

Salesmen and field managers should have a part in the program. Otherwise the men will feel that they are being merely talked to and lectured at. If they have a part in the program they will feel they are an integral part of the convention and that their good work is being recognized.

Contrary to the belief of many, it is not at all necessary that all hours during which the men are not listening to speeches from the platform, be filled with theatre parties, dinner parties or parties of other kinds. To be sure, most men expect that there will be some entertainment during a convention, and would be disappointed by the entire absence of some form of recreation. At the same time, it must be borne in mind that it is the hardest kind of work for an active salesman to sit hour after hour, day after day, listening to someone talk from a convention platform. This is proved by the way men fidget during a convention and by their readiness to get back home when the convention is over.

After an arduous day in the convention hall many men would prefer to go to their hotel rooms and rest. Others want to go to the golf links or take some other form of exercise. Still others thoroughly enjoy getting together with other men, talking over their problems or simply having a quiet evening together.

Too many banquets, theater parties and other forms of entertainment drain the nervous energies of the men. If one does not give them an opportunity to rest he will have a heavy percentage of sleepers during the latter part of the convention.

If a banquet is planned, the men who are to speak should be notified in advance and the others should be assured that they will not be called on for after-dinner speeches. Those who have to do considerable public speaking are apt to overlook the fact that many men stay away from conventions as a matter of policy lest they may be called upon to say a few words. They may be seen at conventions, appetites gone, color gone and having a thoroughly miserable time.

Unless one is calling on an experienced speaker, one should not ask one of the salesmen to get to his feet and "say a few words to the boys." Most of them do not know what to say, and as a result do not say anything except a few banalities and common-places. Such speeches only clutter up the program and make the speaker feel like an ass. It is far better to assign a definite topic to the man and ask him to tell the boys what he knows about that subject. One should pick out something about which he is sure the salesman is familiar and for which he has some liking and enthusiasm.

One should avoid vast general subjects such as "Why I Like This Business" or "The Future of this Business as I see it." Instead, one should have the men talk on such subjects as "How I sell Models 231 to Banks," "The Three Closing Arguments I have found most Effective," "How I Landed the Contract for the A B C Company."

In introducing a speaker one has to be careful not to steal all his thunder by stating the main conclusion of his talk or even the principal points of it. This robs the talk of all freshness and surprise, with the result that the salesman begins his speech feeling that the story has already been told.

In the case of small conferences men can often be induced to talk and timid speakers encouraged, if the members of the conference gather around a table, and if the speaker is allowed to remain seated.

Distracting Attention from the Speaker. If those in charge of the convention remain on the platform during the speeches they should at least appear to be interested in what the speaker is saying, even though they may be bored to extinction.

If they allow their gaze to wander over the hall, if they talk among themselves or take out papers to read, the men will look at them instead of the speaker.

If a book is being explained and demonstrated page by page, from the platform, the speaker alone should have a copy. If the conference is a large one there should be numerous charts or large photostats so that all the men can see plainly what is being talked about. The books themselves should not be distributed until after the talk. If they are passed out before the talk or during it, the men will start to look at the books, pay no attention to the speaker and thereby lose nine-tenths of his message.

In selecting a convention hall, the greatest care should be taken to get one which is quiet, well-ventilated and of the proper size. It is exceedingly tiring to speakers and distracting to the attention of the listeners if there is a constant disturbance from street noises, elevators or running machinery.

The hall should be so ventilated that the air can be kept pure and fresh without drafts.

If the room is too large the speaker's voice will echo and the men are apt to feel lost. If, on the other hand, it is too cramped, there is certain to be discomfort and bad ventilation.

Recesses should be given as often as necessary in order to keep the men alive and awake. Those who warm office chairs are perhaps accustomed to remaining seated for hours at a time, but the salesman who is supposed to be scuttling around the streets, making active use of his legs, grows exceedingly restless if recesses are too infrequent.

The men should get out of the room and outdoors. Someone should be appointed to put them through vigorous setting-up exercises. Five or ten minutes spent in this way will pay big dividends in increased interest and enthusiasm.

A sales conference, large or small, can be of the most fascinating, absorbing interest—an event never to be forgotten and often referred to, or it can be the most tiresome, time-consuming experience in the lives of the men attending it.

If a convention is successful it can be capitalized by making frequent reference to it in subsequent letters, bulletins and house magazines. The talks can be printed and issued at intervals so that the men will be able to review them at their leisure. If, on the other hand, a convention is a failure, the best thing to do is to forget it, with the resolve that next time the convention will be better.

Attitude of Men Influenced by Home Office. How men will react to a convention is largely a matter of policy on the part of the home office. If it has been the custom to hold meetings made up mostly of poker parties, carousals, excursions, and comic talks, the men will get to look for these things whenever they are called to headquarters. If on the other hand, they understand that they have been brought together for a serious purpose, that the convention is costing the company thousands of dollars a day, and that it is being held in order that the men on the firing line may become better and more efficient, their attitude will be wholly different.

Conventions have been held that have represented the hardest kind of work and the closest attention on the part of the men, from one end of the week to the other. At some of these there has been only a minimum of entertainment—a smoker, or possibly a simple banquet—and yet men have gone away expressing heart-felt appreciation of the good time that was given them, and gratitude for the help and inspiration they received.

The vital importance of careful planning and efficient management needs emphasis. Nothing will kill interest and enthusiasm on the part of the men so quickly as signs of indecision, changes in the order of the announced program, failure to make provision for circumstances that should have been foreseen.

If men are not properly taken care of when they arrive in town, if they are herded together in uncomfortable quarters, and if they see the heads of the business looking worried, running about in distraction, and failing to measure up to the situation, their estimation of the house will take a decided drop.

Sneering remarks will be made that the company is playing true to form, that it is no wonder goods are not shipped on time, or that it is impossible to get prompt answers to correspondence.

On the other hand, few things inspire such admiration and enthusiasm for a company and its message as a convention program, particularly a large one, which is run with military precision and clock-like regularity. It is a matter for pride indeed when the selling organization compliments the house on the efficient manner in which a large convention has been conducted. Such a convention is successful and the officials in charge may know that it has attained the objective set for it.

SALESMEN'S EQUIPMENT

By R. J. COMYNS, *Manager Membership Service, American Management Association*

Discussion of the salesman's equipment without regard to a specific product or line is necessarily broad. It is most useful when devoted to a statement of generally applicable principles rather than to illustrations which, no matter how profuse, could be applied directly by only a fraction of those seeking solutions to their equipment problems or improvement in the equipment at present provided their salesmen.

The term "equipment" includes everything that the salesman carries to aid him in making the sale, even to the advance cards and business cards provided by the house. It means very different things in different sales organizations. It ranges from the prospectus of the bond salesman to the ten or fifteen trunks which must still be carried by salesmen in some lines. It may mean the product to be sold itself, sometimes with accessories for demonstration. It may mean working models, a line of samples, and in other cases, catalogues or binders of illustrative literature. The term also includes those report forms and materials furnished the salesman to facilitate his keeping contact with the house and performing the duties assigned him, but the form and content of these need no detailed discussion here.

There are two fundamentals to be striven for; *convenience of form and force of selling appeal*. Equipment is designed to grip the prospect's attention, arouse his curiosity and appeal to his imagination. It should enable the salesman to illustrate the points made in his selling talk and, on the basis that "one picture is worth 1,000 words," drive home his selling points more effectively.

The salesman's talk appeals to the prospect's sense of hearing. Equipment is designed to bring into play those other senses—sight, touch, smell, and taste—to which it is advantageous to appeal in the sale of any particular product. It is designed to visualize the product for the prospect and more especially visualize as vividly as possible, his advantageous, pleasurable or profitable use of it. Needless to say, unusualness and pleasing appearance have a psychological value.

Physical Form of the Equipment. If the salesman must carry his equipment throughout the day, care should be taken not to overload him. It is so easy to add just one more piece without visualizing the total effect. Three

o'clock fatigue is a very real thing with the salesman carrying an equipment bag or sample case throughout the day, though he himself may not realize it. It saps his energy and a tired salesman is likely to lack forcefulness. Greater care than is usually exercised should be taken to make handles of sample cases and equipment bags comfortable to the salesman's grip.

If the salesman travels constantly by automobile, this matter of weight is not so important up to a certain point, though it must be realized that the salesman must often park his car a block or more from the place of his call and oftentimes has considerable distance to travel inside the building. And even in cases where equipment must be carried but a short distance, awkwardness should be avoided. It is difficult for the salesman to appear dignified and make the right approach if he is weighted down with an unwieldy burden. If a salesman must carry a heavy machine into an office or store for demonstration, provision should be made for carrying it easily and comfortably. When, because of the nature of the machine, this cannot be accomplished, the salesman must be instructed to pick his spot the moment he enters and put his machine down before really making his approach.

Compactness is almost as important as weight. In fact if, without impairing effectiveness, the salesman can be supplied with equipment which can be carried in his pockets, this should be done. While it is not well to emphasize or even admit any disadvantage in an equipment bag, it cannot be gainsaid that it is becoming increasingly difficult to get in to see certain classes of prospects, especially in large cities; and reception clerks, telephone operators and even office boys do at times, after one glance at what is obviously selling equipment, accord a special brand of courtesy reserved for those who obviously have not called to buy anything. However, the equipment bag or sample case cannot usually be avoided.

While equipment, to be kept fresh, must be protected, protective material aside from the equipment proper should not be allowed unnecessarily to increase bulk. The loose-leaf binder which does not, because of its mechanism, take up too much room still remains to be developed. Leather covers increase weight and size of equipment. Both should be used sparingly. Binders used should allow the equipment material to lie flat and to be easily turned. At times, an easel-like binder, which may be set up on the prospect's desk and allow the presentation to take the form of a chart talk, is effective; but in case the prospect is likely to be embarrassed by having others know that he is in the process of being sold something, it should be avoided.

Though the material used by the salesman in his presentation may be found in the company's customer literature, it may still be wise to prepare a special piece of equipment for selling work. This will avoid the necessity of the salesman carrying three or four books or booklets in order to use a page or two in each and will also afford an opportunity to make the material more suitable for presentation work as regards type size, layout and general visibility. A type which might be quite suitable for a prospect to read is seldom ideal for material which must be placed before a prospect by a salesman.

While variety will keep the prospect's interest fresh and while dead sameness is to be avoided, the equipment should not look like a hodgepodge of unrelated material.

In equipping the trunk-line salesman, special attention should be given to packing and unpacking and accessibility of individual contents. Adequate protection should be provided for samples with minimum effort on the part of the salesman. Sample lines for a current season's selling cannot ordinarily be replenished, at least not in time if the salesman is traveling fast in a busy selling season. If goods lend themselves to effective display fastened in trunk trays, attractive display will be assured and the salesman will save time and effort in setting up in a sample room. Of course, wardrobe trunks have largely solved the problem of ready-to-wear lines. Care should be taken that no one trunk exceeds the railroad weight limit and that excess baggage is generally held to a minimum.

Special attention should be paid to *seeing that the equipment is kept fresh*. It has a tendency to become dog-eared and unsightly so gradually as to escape the salesman's attention when he is handling it every day. One evening a week or a month should be set apart when the salesman will go over his equipment and replenish with fresh material.

Equipment Bags and Sample Cases. If the bulk of equipment will allow it, the envelope type bag with no more than two gussets, if they be necessary, is to be preferred to the bag with a handle. It is less obviously selling equipment. A prime requisite of the equipment bag is that it be capable of being quickly and unostentatiously opened. A salesman, seated before a prospect, struggling with the buckles of straps is a sorrowful object. Two ordinary lift-the-dot fasteners will usually be found effective. The zipper or talon fastener has possibilities. The bag should be so constructed that once opened it remains open. The salesman should be able to produce equipment from his bag, either on the desk or on the floor beside his chair, without taking his eyes off his prospect or otherwise interrupting the flow of the presentation.

Sample cases should be constructed so as to be as light as possible in themselves. Easy opening is again a requisite feature. In so far as possible, the arrangement should be such that the goods are arranged for display right in the case. Either in the sample case or in the equipment bag, a place for everything and everything in its place is fundamental. The salesman should be trained to put the material back in such a manner as to have it ready for the next prospect without the necessity of rearrangement. This should be made easy without too many partitions or compartments which add to bulk and weight. Frequently it will be found best to have the equipment bag or sample case especially constructed to meet the particular needs of the line rather than to depend upon those which can be found in stock.

Substitutes for Samples. The development of the printing, engraving, lithographing, embossing, and other arts has done much to obviate the necessity of carrying full sample lines and to reduce the bulk which must be carried by the salesman. Today one rug, or corner of a rug or other floor covering for each quality may be carried and the rest of the line shown in a book of beautifully colored and natural-looking designs. Fabrics of all kinds can be pictured in a marvelous way, even those with raised design being shown with absolute naturalness by an embossing process. New methods are being developed every day to tie in with this tendency of cutting to a

minimum the bulk which the salesman must carry and to substitute pictures for actual goods. The sales manager should have in mind constantly these possibilities both for cutting his equipment costs and for lightening his salesman's load.

Working Models. Wherever the product lends itself to this possibility working models may profitably be developed. One illustration will suffice. An organization producing a movable rack for the efficient handling of drums of oil, acids, and other liquids provides the salesman with a small model reproduced in minute detail and a small drum so that the actual working of the device can be demonstrated right on the prospect's desk. Many machines and other products are sufficiently small in themselves to be carried about for demonstration. In that case every accessory for efficient demonstration should be provided and made accessible with a view to allowing the salesman to slip easily, quickly and naturally into the demonstration. If there is any awkwardness or fumbling at this point, he is likely to be asked not to make it.

Photographs and Moving-picture Machines. Modern photography offers many effective possibilities in the field of equipping salesmen and they should not be overlooked. At times, actual photographs convey an authenticity and create a confidence not so easily obtainable by any other type of illustration. Their possibilities are almost limitless. Incidentally, a modern, folding type of the stereoscope which was to be found in every farmhouse parlor of the nineties is being used today to add a third dimension to photographs and to rivet the prospect's attention on the details of the picture.

Where it can be used, the small moving-picture projector combines many of the advantages of the photograph, the working model, and the demonstration and presents in interesting action many things that the prospect could formerly learn only from the salesman's talk. Here again, ease of carrying is a factor and ease and speed of getting into action essential.

Letters of Endorsement. As a matter of fact, the use of endorsement letters is confined to a comparatively few selling propositions. Actually, they have a wide and effective application in fields where they are never used. Care must be exercised to see that each letter says something succinctly and forcibly. This can be accomplished by actually writing the letter and asking the user of the product to sign it or by picking up some statement of commendation he has made and asking him to put it in letter form. The salesman should be encouraged to supplement those with which he is provided by local letters from his territory. A mere copy of a letter will not carry anything like the same psychology as an actual reproduction. For small organizations, they should be photostated. For large organizations, letters can be exactly duplicated as to type, style, ribbon color, letterhead, signature, and paper so as to be scarcely distinguishable from the original. A variety of the endorsement letter is a number of photographs of outstanding installations which speak for themselves.

Charts and Statistics. The ordinary prospect is not figure minded. Quotation of a mass of figures and statistics will leave him in a maze. When statistics and figures are necessary, therefore, they should be illustrated by quickly understood and interest arousing charts, graphs or actual pictures.

The figures and statistics may be clear to the salesman and sales manager. It is best to make sure that they are equally clear to the prospect.

In the sale of any proposition which will allow of it, there should be one piece of equipment in the form of a spread, approximately the size of the ordinary desk blotter, outlining the whole sales story. This will enable the salesman to visualize the story for the prospect but, probably more important, it can be spread over other letters and papers on the prospect's desk and thus prevent their diverting his attention.

Acquainting the Salesman with the Equipment. It is not enough to place the equipment in the salesman's hands. He must be informed of the reason for each piece, instructed in its use and trained in facile handling of it. This will be an integral part of the sales training system. When salesmen are recruited and obliged to study for a period before active connection or coming into training class, each piece of equipment can be mailed one day apart starting with the bag. Attached to each will be a slip "selling" the particular piece of equipment, instructing the salesman in its use, giving the reason for its existence and tying it up with the sales manual which the recruit will be studying at the same time.

Equipment Not a Static Problem. In this discussion of equipment, the endeavor has been to secure the constructive thinking of the reader on his own specific equipment problem by discussing the broad fundamentals involved. Equipment should never be static. The progressive sales manager will always be looking for new ideas which can be used effectively, and constantly developing or improving pieces of equipment.

SALES MANUALS

By R. J. COMYNS, *Manager Membership Service, American Management Association*

Preparation of a sales manual, both as to form and contents must, of course, be considered in relation to the nature of the product or products, selling problems, marketing channels, type of salesmen and sales training methods of the particular company for which it is to be compiled.

What the Sales Manual Is. One of the biggest needs of business, for purposes of scientific discussion, is a common understanding of terms. The term "sales manual" is at times applied to literature designed wholly or in part for use with the prospect. This discussion will be confined to that written record of the experience, policies and practices of an organization designed exclusively for the instruction, guidance and inspiration of the salesman. The life insurance man's rate book, the hardware salesman's catalogue, the wholesale grocery salesman's price book are not sales manuals. They constitute selling equipment.

This should not be construed, however, to call for needless repetition in the sales manual. If, for example, no different, more detailed or more technical description or discussion of the products than that contained in the company's customer literature is required for the salesman, that literature should simply be declared a part of the sales manual and instructions for its study given. In many instances, at least, nothing better can be provided for the salesman than

the description and indicated uses of the products prepared for the customer. If, as is sometimes the case, the sales manual contains detailed technical information and formulas which the salesman cannot hope to carry in his head and the salesman must consequently carry his manual with him on his selling calls, faulty form and compilation is indicated. The obvious solution is to separate physically those parts which are purely sales manual and those which are purely selling equipment.

What the Sales Manual Should Be. Ideally, the sales manual should be a statement of all that experience has proven best in the sale of the company's product, a thorough explanation and exposition of the company's policies as they apply to sales, and a complete guide for the salesman in the performance of his every duty. Few reach this ideal. The sales organizations not provided with any guidance other than that passed on by word of mouth are in the great majority. Most manuals in existence are incomplete and inadequate. Quite often the sales manual is merely a nebulous something in someone's mind which is going to be whipped into shape when the time is available—and which can be dashed off in three or four evenings of concentrated work. Frequently, there is no one in the organization combining the type of mind, necessary knowledge and time to prepare one. It is a mistake to regard the preparation of a sales manual as anything but a full time job while it is being compiled.

Uses of the Sales Manual. A consideration of the uses to which a sales manual is to be put will do much to dictate its contents and form. It should constitute the main textbook of any formal course of sales training given. While it cannot contain in full detail everything given to salesmen in the training course, it should be a digest which will remind the salesman of those details after he is in the field. The sales manual together with a study of sales equipment, may constitute the only training given the salesman. In some cases, this must be so. Sometimes it is planned to be studied by the new salesman before he enters the training course—especially those portions containing the standard selling talk, instructions for use of equipment, and details of the product or products to be sold. And it should be a source to which the older salesman returns again and again for stimulation and to be reminded of things forgotten.

What the Sales Manual Should Contain. Naturally, the contents of sales manuals will vary. The following outline is designed to be suggestive and rather all inclusive. Not all manuals will cover all of the topics mentioned. Some may require one or more not mentioned. The manual may contain:

Introduction. Stating the purposes of the manual, selling it to the salesman and giving instructions for its most efficient use. This, if possible, should be inspirational.

History of the House. This may contain some reference, historical or otherwise, to the industry as a whole. The small beginnings of the business; the courage, industry, integrity and far sightedness of the founders; development and constant improvement of products; physical growth; present standing in the industry; outstanding executive personalities of today; are some of the topics which may be touched upon here.

The Products. Description of the products; unless, as has been suggested, this is adequately covered in other literature.

Uses of the Products.

The Standard Presentation. The word "presentation" instead of the more widely used term "selling talk" is used here advisedly. A sales presentation is not merely a talk but a combination of talk with the effective use of selling equipment, and the standard presentation should include instructions for this. There is vast difference of opinion as to the value of a so-called "canned" presentation. Not every product lends itself to a standard presentation given each time in the same way and with the same balance and emphasis. The fact remains that anything which one must say frequently is inevitably said in much the same way each time. There can be little question that the strongest, most concise and most effective ways can advantageously be worked out for the salesman, if only as a basis for developing his own method more quickly and more effectively than would otherwise be possible. Though each individual presentation may be somewhat peculiar to itself, every one that a salesman makes tends to become an assemblage of standard parts. In so far as is possible, the sales manual should provide these standard parts.

Notes on the Standard Presentation. One of the commonest tendencies of salesmen is to get down to a presentation of bare facts to the exclusion of those imaginative and emotional appeals which really sell goods. An explanation of the reason for their being included in the presentation will tend to prevent this. Many things may be said with equal effectiveness in more than one way. Suggestions may be given for the elaboration of certain points. Instructions as to emphasis may be desired. Suggestions may be given for handling situations which may arise at given points in the sale. To interpolate these in the standard presentation itself would tend to break its continuity and render it difficult to read and study consecutively. Providing for reference to numbered notes will obviate this. If the form of the manual otherwise lends itself to it, a good plan is to have the presentation run along continuously on left-hand pages with corresponding notes on the right-hand pages. This will necessitate some careful editing so that presentation and notes are of approximately the same length.

Instructions for Demonstration. In the case of products where demonstration is essential, desirable, or possible.

Handling Objections. The term "handling" is used advisedly in place of the more common "meeting" or "answering." Many objections should be anticipated rather than answered. Most sales manuals make the same mistake of listing objections and giving for each one a perfectly logical answer but one which is a head-on collision and an argument. Sales are not made that way. All objections and questions need not be taken with equal seriousness by the salesman. The astute salesman's aim is to handle the objection or question as briefly as possible, slip around it, and get back on the track of positive presentation of the advantages of his proposition. While this is a difficult thing to get into the printed word, it should be kept in mind in preparing this portion of the manual.

Sales Equipment. A discussion of each piece of equipment supplied the salesman for field work with suggestions for handling, most efficient use, arrangement and replenishing. This will include instructions or suggestions for the display of sample lines.

Reserve Selling Talk. Every salesman needs selling points in addition to those furnished him in the standard presentation and in answers to objections. On occasion, he needs ability to approach the same selling point from several different angles. Especially is this true when, after an attempt to close has failed, he must swing into additional reserve talk before attempting another close. This section may contain more or less complete presentations from

an angle other than that of the standard, side lights or stories which illustrate points, and effective methods of closing the sale. A separate section on closing tactics may not be amiss.

Seeing the Prospect. Many sales manuals and some training courses blithely ignore one of the salesman's greatest problems—that of being able to see and get his story before an adequate number of prospects each day under proper conditions. This section, for most products, can well go into considerable detail on methods of approach, handling difficult situations that arise in the first few moments of the interview, effective methods of getting into the prospect's office or otherwise creating conditions favorable to the interview, the effective use of the telephone in making appointments, and the like.

Organization and Handling of Territory. This may include instructions for building a prospect list, discussion of the different types of users of the company's product and the appeals which may be made to them, efficient routing and use of time, depending on the nature of the business.

The Company's Advertising. The salesman will or should receive continuously from the advertising department information as to current advertising, but he should be given in the sales manual the reasons for the company's advertising policy, type of copy, selection of media, and specific instructions on the part he is expected to perform in the company's advertising plan and how most effectively to talk advertising to his customer.

House Policies. The salesman should be given in the manual knowledge of the other departments of the inside organization sufficient to enable him to cooperate effectively with them and to make him feel that he is an integral part of the organization. Possibly an organization chart should be included. The company's trade practices, discount policies and the like should be discussed here.

Manufacturing Processes and Policies. In many cases, such a section may not be at all necessary. But in others, some information of this kind is essential to the salesman. Care should be taken, however, not to make it too technical and detailed.

Rules and Regulations. Under this heading, the salesman should be given detailed instructions as to what is expected of him in the matter of reports, expense accounts, handling of orders, opening of new accounts, credit information desired of him, and his rights to credit for business should be clearly defined.

A formidable list—not all of which, fortunately, will usually be necessary. Some would feel that, in addition, instruction in the principles of salesmanship should also have a place. It is doubtful, however, if the subject could ever be treated with the same effectiveness in a sales manual as in any one of a number of good treatises on the subject which may be supplied to the salesman separately if desired. Some large organizations, of course, have been able to have textbooks or even complete courses in salesmanship prepared especially for them. Others might feel that a section on dress, appearance, voice culture, industry, courage and avoidance of bad habits should be included. Possibly so, but it may easily be overdone. Business would seem to be getting away from the too paternalistic and preachy stage. The high-class salesman resents it and, in most instances, reasonable care in these matters may be taken for granted. Furthermore, few star salesmen possess all the virtues and we are likely to be embarrassed by outstanding men who violate our righteous precepts.

Sources of Material. In every organization which has been running for any length of time, the material for the manual is in existence either in some written form or in the minds of the personnel. The problem is one of selection, organization, compilation, and putting the material into good literary style. The training methods of the organization, no matter how crude and irrespective of how little has been reduced to writing heretofore, will furnish the basis. It might be well, as a preliminary, to have stenographic reports taken of the talks given in training class. If the organization has published for any considerable time any type of publication for salesmen, it should be replete with valuable selling suggestions. The proceedings of general or sectional sales conventions and conferences should not be overlooked. The sales manager's letters to his men should be a prolific source of ideas. This material will be supplemented by information gathered directly from the salesmen in the field. They may be asked to contribute their best selling talks and most effective selling points, the methods they use in approaching and handling prospects, their reserve talks and methods of closing. They will be asked to state the objections they find most difficult to overcome. These objections may possibly then be grouped according to types of prospects and those salesmen most successful with each type asked to give their methods of handling these objections. Branch managers and sales trainers in the field will be called upon for contributions. Many of the portions having to do purely with the inside organization will be written by men in the several departments. Editing will be necessary here for balance and homogeneity of style.

Who Shall Write the Manual? Seldom will the sales manager have either the time or temperament to compile a sales manual. The man selected should combine some knowledge of and a keen interest in sales, should have something of a research type of mind, a keen reporting sense and a forceful, direct, and possibly dramatic writing style. If a man possessing this rather unusual combination of qualities can be found in the sales organization and brought to his task fresh from his field experience, so much the better. If a man is selected from the inside, it may be well to send him out for a period of selling experience, observing experienced salesmen work, preliminary to starting actual work on the manual. If a man is brought in from outside the organization, adequate time should be allowed him to study the organization on the inside and selling methods in the field before actual work of compilation is started; and every facility should be afforded him to gather information both from records and people.

Physical Form of a Manual. The manual need not necessarily be elaborate in form adequately to perform its functions. In a small organization, multigraphing or mimeographing serves the purpose. Readability, however, is important. Many organizations, most careful about the typography of literature going to their customers, feel that a sales manual may be printed in crowded, fine type. Adequate-sized type, proper headings, right length of line, and general attractive appearance will have much to do with the extent to which the sales manual is read and studied by the salesman.

The sales manual has been spoken of here as though it were necessarily included in one volume. That is not always so and is not at all desirable if

the material included in it bulks large. A salesman may be somewhat appalled by the prospect of having to wade through a three hundred page book, but digests the same material from a number of unostentatious, paper covered pamphlets without feeling it at all formidable. Furthermore, this form of several small manuals makes for greater elasticity, especially where parts of the manual must be studied by the recruit prior to his entrance upon actual employment or training. They are especially effective where training must be given in non-residence.

On the other hand, a loose-leaf manual, with the page numbering of each section starting from one, and each page bearing the name of the section as well as the page number, allows for frequent changes and additions. In most instances, however, this will be found more theoretically than practically desirable. A compromise is to put that portion of the manual subject to frequent change into loose-leaf form and the balance either into one permanently bound book or into several pamphlets. Inasmuch as the manual is to be studied by the salesman at home or in training class, no consideration need be given to making it pocket size. On the other hand, larger size makes for readability and the possibility of illustrations, where they are necessary.

General Observations. It is a mistake to believe that the selling portions of a sales manual can be written in an office. They are merely compiled there. They must reflect actual and practical field practice and experience. No pure theory should be advanced as anything but theory until it has had actual field test. No hobbies of particular managers or executives should be ridden. Methods of sales to be selected should be those fitted to a wide range of personalities. If the successful method of a star cannot be separated from this particular personality and reduced to terms of the average salesman or at least of a large number, omit it, no matter how reluctantly. It is better not to mention salesmen or even district managers by name in the sales manual. This is well enough in the sales bulletins and the sales manager's letters to his men but individuals have a habit of leaving an organization, not always pleasantly, or otherwise discrediting their methods in the eyes of the sales organization.

All suggestive sales talks, methods of approach, telephone talks, reserve talks, and closes should be put in direct quotes—from the viewpoint of the salesman actually talking to the prospect. It will be found that most salesmen are not particularly adept at interpreting indirect suggestions into direct quotations and statements. It should be given to them in exactly the form in which they are to use it with the prospect.

While the sales manual is in course of preparation, it should be sent to all salesmen in the field section by section, with the statement that in its final form, it will be their sales manual—not the manager's. They should be asked to read each section and to send in their comments, criticisms and suggestions for improvement, either noted on the copy or in a separate letter. The most important effects of this are that it insures the manual being read by the older men in the organization and prevents their criticising it later as theoretical or office made. They have had their opportunity to make it theirs before it was put in final form.

It can not be too strongly emphasized that the sales manual which would be effective is worthy of the care, consideration and cooperation of every execu-

tive and department head; and of the finest, most forceful writing, rich in human interest and dramatic appeal, procurable. That may seem over-emphasis but, because of the lack of those things, most sales manuals fail of maximum effectiveness.

It will be realized, of course, that in a sales organization employing branch manager, coaches or field trainers, or crew manager, separate manuals must be provided for them.

EXPENSE ACCOUNTS OF SALESMEN

BY WILLARD E. FREELAND, *Vice President, Freeland, Bates and Lawrence, Inc.*

Little standardization has appeared in the manner in which salesmen's expenses are reported, checked, analyzed, and controlled. The treatment of expenses by different companies is highly individual. By some companies, reporting and analyzing are carried out in great detail; by others, the problem is met by giving flat expense allowances based upon experience data.

A common trouble is to get expense reports filled out properly and sent in promptly. The process of constantly nagging the salesmen accomplishes little and may hurt the morale of the organization. So other steps and expedients have been sought to better the condition. One step is to make the reports more simple and more convenient to fill in and to carry. Another device is to combine various required reports in one sheet in coupon form so that the expense report, the daily activity report, requests for advertising and sales promotion help, etc., are combined in one sheet and come in together.

Current Practices and Methods. As marketing management moves toward a more scientific attack upon its problems and, particularly, as it begins to include cost accounting as one of its working tools, there is evidence of more detailed reporting and analysis of expenses. The items formerly lumped under sundries begin to appear in more specific forms and various expense standards make their appearance.

It is quite common to find in manuals of sales policies and standard procedures, or in house bulletins, schedules of maximum allowances for various major classes of expense items. Such standards as these are usually based upon experience. As more research is applied to the study of allowances, one notes that the maximum allowances are established for differing types of territory and for various sizes of towns.

Another practice becoming quite common is to make use of comparative analysis sheets of the expense items as a means for establishing better standards and for discovering the trends of various classes of expenses as one means for better control. In the larger sales organizations these comparisons are valuable for studying the expenses of the men within one division or sales district, the relative expenses of men in comparable types of territory, the totals or averages of expenses of groups such as sales districts, or the effect of better methods of sales operation such as planned routing, or selling to small towns or customers by making more use of the mail or the telephone in place of personal calls.

Use of the Flat Allowance. While there are no reliable figures available to warrant the statement that flat allowances for expenses are increasing in

favor and use, the increasing amount of published discussion of the question would indicate a wider adoption of fixed expense allowances. The flat allowance is usually upon a *per diem* basis but in some instances is upon a weekly or monthly basis.

The advocates of flat allowances claim that this method, which does away with expense reports thereby eliminating all the labor of checking and virtually all disputes, is fully as effective as any detailed reporting system and definitely adds to the morale of the sales force. Those opposed to flat allowances claim that under such a system the salesmen are inclined to live at cheaper hotels, buy cheaper meals, etc., in order to add to their own income from the fixed expense allowance and that this process eventually changes the perspective and weakens the selling ability of the man. The advocates reply that a man who would do this under the flat allowance system would and did cause the same trouble under the old arrangement.

Treatment of Certain Expense Items. Among the most troublesome of the expense problems is the item of *entertainment*. In the old days the item of entertainment was not large nor was it under suspicion as a step in the selling process, so today it is in the older industries and the older sales organizations that the entertainment item is most under fire because it is in those industries that it has become a great abuse. Legislatures and trade associations are working against the entertainment of the buyer as a dangerous form of commercial bribery. Many companies no longer have a place on their expense reports for entertainment and when a salesman does have to report an entertainment item, he has to make out a special report in great detail. It is interesting to note that in many cases not even the friendly cigar is able to find a place for itself on the expense report.

The item of *laundry* is another expense item which has not won general acceptance as an expense which the company should assume. It does appear among the legitimate expense items of many companies, based upon the belief that it pays to encourage the salesman to maintain a good appearance and that costs for laundry and pressing are returned by increased sales and goodwill.

The expenses for *sleeping and chair cars* present another expense problem. Most companies now cheerfully allow for lower berths and there is an increasing use of the section in the belief that more rest secured at night will pay dividends in sales the next day. There is more discrimination, however, about expenses for chairs. The majority of companies establish some factor of minimum distance before they will accept a charge for a chair.

So one might go down through the list of other expense items such as tips, taxis, requirement of receipted bills, and similar expenses and find no common agreement as to how they should be handled. Many companies issue rules governing such expenses. The only general observation that can be made is that where high-grade salesmen are employed these expenses are quite generally recognized and permitted; where low-grade salesmen are employed these items are usually much restricted.

Expense Cost Reduction Methods. One common practice is to assign a headquarters town to a salesman and to assume very little expense for the salesman while he is working in his home city.

A growing practice is to plan the routing for a salesman which has been found an effective method to reduce traveling expense and to increase the amount of time spent in actual solicitation of business.

Another method is to hold frequent, friendly conferences with each salesman to review the expense accounts. This process of education has been found to give good results.

Rigid scrutiny of expense items and continuous reporting to the salesman of errors and excesses is a very common practice in large sales organizations and in many cases has apparently been successful without arousing too much resentment. In many companies the salesmen are made aware that expense accounts are checked by the sales manager, the treasurer, auditor, or other official, and this method unquestionably has an effect in holding down the total expense.

Various graphical methods of presenting the salesman's expenses relative to those of other salesmen, particularly of those working in comparable territories, has been found effective without having to resort to much discussion or correspondence about specific items. Sometimes it has been found possible to establish a standard for the expense per dollar of sale for each salesman which they will accept as a fair standard and then show by graphical methods the variations from standard and the trend. This method is sometimes very effective.

Sometimes it pays to discuss with a salesman that the problem is not one of traveling expense solely; that the real problem is one of total cost for salary and expenses. It can be made plain to him that if expenses run high his opportunity for salary increase is reduced.

There are various methods by which the sales quota is made a part of the expense picture and a salesman has a chance to increase his bonus by keeping his expenses as low as possible. In some instances there is a specific bonus offered for reduction of expenses. This bonus is usually made payable at the end of the year.

Yet another method to check extravagance in expenses is to establish some method by which the salesman will automatically discover when his expenses are running out of line. One way to accomplish this is to have the salesman compute for each expense report sent in his average cost per call or his average cost per unit of sale or per dollar of sale. These computations can be made in the home or district office and furnished to the salesman but the effect is probably not so good as when he makes his own computations.

Expense Analysis. There is no end to the possibilities of method in the analysis of expenses. Very little work is required to carry on some analyses in which a sequence of averages over successive periods of time is determined in order to have a basis for fair comparisons and to ascertain definite trends. The averages computed monthly to ascertain the daily averages for total expense, for hotels, meals, transportation, and other classifications is worth while in any sales organization. It helps to remove the danger of commenting to a salesman about an expense item on a particular report while the manager is actuated by impulse or whim. Comparison with a standard might show that ordinarily the salesman kept this particular item under close control and the language of the comment made might be much tempered by the recognition that the item was an exception.

Automobile Expense. Here is a subject of great interest to most sales managers but one so complex and so little standardized that an entire book might well be devoted to its discussion. The larger automobile companies are able to give a great deal of specific information on the experience of sales organizations and the methods by which they analyze and control such expenses. Various research organizations have made studies of automobile expenses and expense control methods and these are available to those who wish to make an exhaustive study of the expense problem presented by the use of the automobile in sales work.

In actual practice the complexities of detailed reports of automobile expenses are largely overcome by the use of a flat allowance per mile or per day. In many instances there is a flat allowance for the usual running expenses and a flat monthly allowance in addition to cover the matter of depreciation.

There is no common practice with respect to whether the salesman or the company shall own the car. It is quite common to find both methods in use by a single company.

CONTRACTS WITH SALESMEN

BY WILLARD E. FREELAND, *Vice President, Freeland, Bates and Lawrence, Inc.*

Whether it is advisable to have a formal contract with a salesman is an open and, to some extent, a controversial question. There seems to be abundant evidence that the tendency is away from the formal contract. Even if it is not recognized by formal written evidence, however, it is true that a contract is entered into virtually every time a salesman is employed.

The most prevalent use of written contracts is in the field of the sale of office and store appliances and in this field some of the finest examples of the formal contract are to be found. It is also evident that the formal contract is found frequently in those businesses in which salesmen are paid on a straight commission basis, or where the written contract is an inheritance from the days when the commission form of payment prevailed.

Under certain conditions there seems to be a definite need for a formal contract. Typical of such conditions are the following instances: where the ultimate sales are on a contract or time-payment basis; where the protection of important patent rights is involved; where salesmen keep accounts or collect funds; or where the salesmen are hired by distributors.

It is not the written document which constitutes a contract. A contract is entered into whenever there is a "meeting of minds" in an agreement to attain a lawful objective and the agreement creates an obligation or a right. The agreement must be mutual and contain equivalent promises. An element of a contract is that the contracting parties must be legally competent, which means that they must be under no legal disqualification and must be of lawful age and of sound mind. Another element of a contract is that there must be some legal consideration which need not necessarily be money. In view of the number of contracts involving employment and services which

are constantly in the courts, it is advisable to have competent legal advice upon all contracts to make sure that they are legal in form and content and that the language of the document is so definite and clear that only the desired interpretation can be made in case of a future dispute.

Those who are opposed to the use of formal contracts point out in their arguments many disadvantages which seem to them inherent in a written, fixed contract. Much of the argument of the opposition centers around the inflexibility of the formal contract. They claim that it is impossible to foresee all the future conditions and stress the difficulties which arise when it becomes advisable to change basic policies and methods of sales operation.

Statements of Salesman's Duties. One of the first steps in the drawing of a contract is usually to give a promise of employment and to state clearly and concisely the duties which the employee undertakes to perform. Usually he is required to give his whole time to his work as representative of his employer and it has been found especially valuable to include a statement that he is to give his best efforts to advancing the interests and business of the employer. Often a point is made of stating that the salesman is to make every effort to obtain the distribution of the full line of the employer. Also, there is usually a statement that the salesman is not to carry any side lines.

In many cases it is necessary to give to the salesman confidential information and documents and a clause is inserted to safeguard the use of such information and documents and to provide for the return of all confidential documents and records upon request of employer or upon termination of the contract.

If the salesman is required to perform certain service, repair or inspection work in connection with his other duties, the scope and character of such work is defined carefully. If the salesman is required to make collections, this phase of his work is covered carefully and the time and manner in which he shall make remittances of money collected is set forth in detail.

If the salesman is required to use certain standard order or other forms of the employer, this should be covered in the contract. There should be no uncertainty as to the requirements for periodic reports or work done, expenses incurred, or any other required reports such as route sheets, statements of conditions in field or territory, credit reports or information, status of consigned goods, or condition of samples or selling equipment. With reference to samples or selling equipment it is usually advisable to cover all matters relating to damage, loss or insurance. Sometimes it is necessary to cover the item of fidelity bonds in detail.

Statements of Limitations and Restrictions. In most contracts it is essential to set forth the limitations and restrictions covering the conduct and activities of the employee for the protection of the employer. Where one finds these sections of a contract many and varied, it usually is caused by conditions peculiar to the business of the individual employer or because the salesmen are of relatively low grade and pay. Some of the protective sections are found quite generally in contracts because they operate to obviate future difficulties and disagreements. Some of the more common protective sections are discussed briefly below.

One of the clauses commonly found states that an order is not valid until it is approved and accepted by the employer. Another similar clause gives the employer the right to use his discretion about filling orders and often covers the matter of delays or partial deliveries.

The power of the salesman to bind the company is usually covered in definite detail, particularly so in the case of contracts with sales agents.

In many kinds of business it is wise to have a clause stating that the employee binds himself not to engage in the same kind of business for a definite period, usually a year. This is particularly the case where it is necessary for the salesman to have much confidential information about the business of the employer, or where it would be easy for one or more salesmen to engage in such business on limited capital.

In view of the fact that many a contract or agreement exists without being specifically recognized as such by the interested parties, it is common practice to insert a clause stating that the present contract cancels all former agreements. In many contracts are found clauses covering such items as vacations, illness, and absence from the assigned territory.

In many lines of industry or business the matter of "trade-ins"—equipment or appliances taken in exchange for new—is an important element and is defined and clarified in great detail.

It is sometimes essential to define carefully the rights of the employer to have special representatives or other salesmen work within the territory assigned to a salesman working on contract.

Numerous court decisions have made plain the necessity for the insertion in a contract of a section clearly defining when and in what manner a contract may be terminated. It is advisable also to cover such matters as the disposal of the employer's property in the possession of the salesman, the time and manner of settlement of any earned commissions, the question of deductions from any unpaid earnings, and any matters relating to bonuses, prizes etc.

An interesting and important development is the manner in which current manuals of house policies and decisions are being made a part of modern contracts with salesmen. Many of the opponents of formal contracts claim that a simple agreement covering employment and compensation and a signed receipt for a company manual will serve the interests of all parties as well as a written contract.

Statements Covering Territory. It is customary to assign a definite territory to a salesman. In these days of scientific research and analysis it is essential, however, that such assignments be so worded as to permit the greatest flexibility as to location and size of territories. In some types of business, too, it is essential to define or limit the kinds of trade or classes of customers and prospects to be called on or solicited.

It is customary to establish a home or headquarters city for the salesman, usually one relatively near the center of his territory. The employer assumes only limited, minor expenses of a salesman in his home town, but the matter of simplified routing and cutting of transportation expense is also important.

If the employer has established a quota system, all matters into which quota enters should be defined clearly in the contract. If all or a part of the

compensation is computed on a "point" system, this also should be described and defined adequately.

Statements Covering Compensation. The sections of a contract covering compensation are frequently the most difficult to write in clear and understandable language. This is particularly true when the method of compensation is complex, such as a combination of salary or drawing account, commission and bonus. Yet it is essential that definition and description be clear and concise and that, as far as possible, all future contingencies be foreseen and guarded against.

If payment is in the form of commissions, one section should set forth comprehensively all the rates and classes of commissions and the exceptions thereto. It also should describe the accounting periods for commissions and the form and time of payments.

A plain statement of salary is made easily but if a drawing account is involved, the description is usually not so simple. If the drawing account is not virtually a salary and it is expected that it shall be recovered from earned commissions, then it is essential that a statement be included that both parties consider the drawing account as a loan.

If a part of the compensation is expected to come from bonus earnings, then a most careful and detailed account of the bonus system should be written.

If it is proposed that deductions shall be made from earnings under certain given conditions, it is important that all possible phases of the matter be described in detail in the contract. The time and manner of such deductions should be made clear. Some of the usual causes for deductions are repayment of advances, cancellations of orders, return of goods, failure to collect for goods invoiced to customers, and loss of, or damage to, company property.

Another matter which frequently needs clarification is credit or commissions for mail orders from a salesman's territory.

A troublesome question in many sales organizations is the problem of "split" commissions where two or more salesmen are involved in a single sale, or where one salesman takes the order and one or more salesmen in other territories have some form of service work to do in connection therewith. The employer's decision should be stated clearly as final in such matters, but the morale of the organization usually is bettered if standards to cover such problems can be established and made a part of the contract.

If the matter of expense allowances and expense standards can be handled as a part of a company manual of policies and standard procedures, then the expense section of the contract can be made clear and concise by including the manual as a part of the contract and stating definitely that the manual is subject to constant revision and that any particular complaint or controversy shall be settled according to the rulings of the manual current at the time the situation arose. Otherwise the entire matter of expenses must be covered in detail in the body of the contract. Matters connected with the use by the salesman of his own or company automobiles for transportation in his work are usually set forth in adequate detail in a section separate from the other expense provisions.

Other Special Provisions. In some lines of business it has been found advisable to cover in the contract all matters relating to change of prices, terms of payment, and freedom of the salesman to quote special discounts.

In some contracts the precise form of cooperation which the salesman is expected to give to the credit, advertising, sales promotion, and other departments of the business is described in clear terms.

Occasionally there is found in a contract a provision setting forth the details for the renewal of the contract or the continuation of employment.

CHAPTER VIII

SALES PROMOTION

BY GEORGE W. HOPKINS, *Consulting Sales Executive*

"Sales promotion is organized effort applied to the selling job to secure the greatest effectiveness for advertising and for dealers' help." This falls into the following divisions:

1. Securing the most effective dealer use of sales promotion ideas and sales promotion material.
2. The application of advertising to the selling job.
3. Development of advertising material to be sent.
 - a. To dealers.
 - b. To customers for dealers.
4. Development of operating technique.
 - a. In the sales department.
 - b. At branch offices.
 - c. By the salesmen.

The object is to focus the attention of the consumer on the dealer's window and store, thereby getting full value from all advertising and publicity at the point of sale.

Some manufacturers object to the word "promotion" and call it the "sales development department" instead of "sales promotion department." The idea of development enlarges the scope of the department, indicates action, and dispenses with the word "promotion" with its less attractive meaning. Development gives the idea of a department taking off its coat to help the dealer build real volume of business at a profit. But in order to avoid any confusion, we shall use the name sales promotion.

Sales promotion is the connecting link between national advertising on one side and field selling on the other side. It is both a lubricant for smoothing the course of the salesmen's effort and a tonic for increasing the activity of salesmen and dealers in the sale of the product.

In case the business is not large enough to warrant a separate sales promotion department and there is no advertising manager, it is possible for the sales manager to act in this capacity, but he should keep the functions of this department separate and distinct from his sales managing duties. If this is done, as the business grows and an advertising manager is added, some of the work can be apportioned to him, the functions as a whole, however, being kept as a separate entity. Sometimes the sales promotion manager is

appointed to carry on in the field without the support of periodical or newspaper advertising or of an advertising manager. There are many phases of advertising that can be handled by a sales promotion manager, the use of which would not warrant an advertising manager. If three are possible, the general sales manager, the advertising manager, and the sales promotion manager make an ideal sales cabinet and with the functions of each department carefully outlined, there is no crossing of wires, each supplementing the work of the other and through frequent consultation, setting the sales policy.

There are thus three possible set-ups: (1) a sales manager also carrying on the functions of a sales promotion department and an advertising department; (2) a sales manager functioning with a sales promotion manager and taking on the duties of an advertising manager in so far as the business warrants; (3) a sales manager, a sales promotion manager, and an advertising manager. Each department in each case develops in accordance with the kind of business and the volume. It is wise to keep the sales promotion department separate and distinct from the sales and advertising activity, whether it is incorporated in the duties of some official or separated and under its own manager.

The man in charge of the sales promotion department should be a man of imagination, a man who can place himself in the shoes of the dealer, realizes his problems and, while selling him more merchandise, at the same time shows him how to sell at a profit to himself. Such a manager should be a field man in order that he may keep in personal contact at all times with the requirements of the trade. First, he goes out to see what the dealer wants and what he can use to the best advantage. Second, after preparing the window material or store material, he goes back over the same route to see how it is used and what returns it is bringing to the dealer.

It is best to select certain sections as *proving grounds* where a small part of the money to be devoted to this work can be invested and tried out, getting a fair cross section opinion of how the dealer will respond to the material and what results it will bring to him. In other words, instead of spending the full appropriation for a beautiful window trim covering the entire country, buy a small quantity even at a higher price, try it out with a fairly representative group of stores, check them carefully, and then decide whether to go ahead or make some changes. After a try-out of this kind, the sales promotion manager feels positive when he writes the dealer about such display that it will work in his store and why. It is necessary to get personal knowledge and not knowledge that comes through salesmen. A salesman is sometimes too enthusiastic about the amount a dealer can use so long as it does not cost any money, whereas there are some stores where a display will not fit at all and is entirely wasted.

If the sales manager or the advertising manager are doing this work, they must step out of their positions in order to get the viewpoint of the sales promotion manager and his duties. The work is primarily helping the dealer to dispose of merchandise the salesman has sold him. The dealer looks from one side of the counter while the sales manager looks from the other side. It is difficult to see it from both sides and as soon as it is possible, a man should be appointed to take over the sales promotion work.

Mergers in various lines of industry have changed the value of sales positions. Some of these mergers have wiped out competition and with it salesmen, sales managers, advertising managers, and sales promotion managers. These positions have been consolidated in fewer men and, in most cases, in men of higher caliber. Sales promotion has been developed to mean more than it ever did before and the man responsible for sales promotion may have the title of president, vice president, assistant to the president, general sales manager, or sales promotion manager. This does not mean in any case that all of the ideas come from one man, but the man who is responsible for sales promotion has the duty of producing new ideas, must have a vision as to the possibilities of the business, and must be able to put his thoughts into profitable operation. Details of the job may be handled by men and women in the organization, but in every business you will find one man who stands head and shoulders over any one else in the organization in his ability to promote sales at a profit.

What Does a Sales Promotion Manager Do? There follows a tabulation of activities in which every sales promotion manager should be interested. The fact that the sales promotion manager is not a separate entity does not affect this at all. We are outlining the functions of the job regardless of who fills it:

1. Package.
 - a. Form of the package.
 - b. The price.
 - c. The label.
 - d. The carton.
 - e. The insert.
 - f. The counter display carton.
 - g. Method of packing consumer assortment.
 - h. Christmas or holiday package.
 - i. The shipping carton.
2. Service to salesmen.
 - a. Survey.
 - b. Research.
 - c. Sales manual
 - d. Advertising portfolio.
 - e. Paving way for salesmen's calls.
 - f. Writing dealers missed by salesmen.
 - g. Maintaining contact with dealers.
 - h. Letters of welcome to new dealers.
 - i. Handling complaints from dealers.
 - j. Contests.
3. Service to dealers.
 - a. Broadside to dealers.
Order blank.
Return envelopes.
Stamped return envelopes.
 - b. Double post card.
 - c. House organ for dealers.
 - d. Special mail campaign.
 - e. Dealers' meetings.

4. Propositions to dealers.
 - a. Dealer service book.
 - b. Free deals.
 - c. Assortments.
 - d. Window display plan.
 - e. Demonstrating plan.
 - f. Booklet plan.
 - g. Sales plan.
 - h. Special price sale.
 - i. Special price item.
 - j. Standard sales talk.
5. Display.
 - a. Window displays.
 - b. Snipes.
 - c. News posters.
 - d. Giant advertisements.
 - e. Enlargement of advertisement with broadside.
 - f. Store arrangement.
 - g. Counter display fixture.
 - h. Store display fixture.
 - i. Monthly dealer service.
6. Things to do for the dealer.
 - a. Demonstration.
 - By salesman.
 - By temporary demonstrator.
 - By permanent demonstrator.
 - b. Door to door canvassing for the dealer.
 - c. Samples.
 - Free given away by dealer.
 - Free delivered door to door.
 - Free through advertisements.
 - Free through mail from manufacturer.
 - Charged for through advertising.
 - Charged for by dealer.
 - d. Full size package free through dealer.
 - e. Movie tie-up.
 - f. Combination sale of product and allied items.
 - g. Advertising inquiries sent to dealers.
 - h. Letters to consumers over dealer's name.
 - i. Broadside to consumers over dealer's name.
 - j. Missionary sales for dealer.
 - No charge to dealer.
 - Specific charge for the sale.
 - Blanket deduction from discount.
 - k. Prize contests for windows.
 - l. Prize contests for clerks.
 - m. Prize contests for consumers.
 - n. Premiums to clerks.
 - o. Training dealer's clerks.
 - p. School for dealer's clerks.
7. For dealer use.
 - a. Dealers' survey.
 - b. Newspaper cut and copy service.
 - c. Catalogues for dealers' distribution.

- d. Envelope insertions for dealers' distribution.
- e. Booklets for dealers' distribution.
- f. Special price coupon for dealers' distribution.
- 8. Publicity.
 - a. Movie slides and films.
 - b. Metal signs.
 - c. Canvas banners.
 - d. Decalcomanias.
 - e. Store cards.
 - f. Business shows.
 - g. Calendars.
 - h. Fans.
 - i. Blotters.
 - j. Novelties.
 - k. Trade papers.

The Package. In referring to the package we mean the unit offered to the trade. It does not necessarily mean that goods are delivered to the consumer in a package, although in these days most goods that enter the market through jobbers and dealers are offered to the consumer in some kind of package. If it is to appear on the counters of the dealer, than the sales promotion department is vitally interested in its size, its shape, its general appearance, its competitive standing, and in many other ways, for it is largely through the eye that the consuming public makes its purchases. What the merchant may say to the consumer does not create nearly the impression that the appearance of the package makes on the prospective buyer.

The sales promotion department must ascertain through surveys, research and contact with the dealer and factory conditions, what kind of package should be offered the trade.

Form of the Package. This will depend on how the package is offered to the consuming public. If it warrants counter display, shelf display, or window display much care should be taken that the form of the package is as attractive as possible. If it is an article that appears in the home in its original form, particularly if it is a food product and served on the table in its original package, utility should be added to pleasing appearance. Convenience of access to the product should also be considered. In the case of a new vinegar that has come on the market, the three sizes of home containers are beautifully shaped, attractive, and convenient, the smallest size being in the cruet form so that it can be placed on the table and the vinegar served therefrom.

In the cosmetic and toilet goods field it is of greater importance than in any of the other industries that the package should be artistic in appearance.

How convenience, use, utility, and good appearance may be secured will be determined only after a careful survey of the market, particularly before any radical change is made. An intimate knowledge of home as well as of store conditions is necessary before tackling this problem.

The Price. Profit to the manufacturer and to the jobber and dealer is the first consideration in pricing the product. There are, however, "price channels" for every line of merchandise and to step out of these channels even at a lower price will disconcert the buying public to the extent that they will hesitate before purchasing. A careful study should be made of

price channels in the industry before fixing a price on a new product, particularly if this price is a suggestion as to what the dealer should charge.

A manufacturer was offering a high-grade product at 23 cents a pound but was unable to interest high-grade stores. An examination of the product proved that at 23 cents he was in the price range of competition with low-grade products and lost the benefit of the quality of his product. When he raised the price to 45 cents, he entered a field where his product was equal in every way to the competition and immediately he was able to open the high-grade accounts. He continued successfully selling through these stores to the public. In the first place, no survey of the market was made or the situation would have been discovered. By no means is it always the lowest price that wins business. It is well to remember the saying, "Price determines quality." Price is the only measure of quality for most people. Many persons can not detect the quality of fabrics, foods, or hardware, and most of the buying public reason that the higher price means the better quality.

A product that is to retail for a price under \$1 usually falls within the one coin price, that is, 5, 10, 25, or 50 cents. Many times a product will sell better at 25 cents than at 20 cents, for the reason that the purchaser passes out one coin at 25 cents whereas in 20 cents it is two coins or more. Custom has established the one-coin price under \$1.

The Label. The appeal of color is primitive, especially that of the primary colors. Color in the package appeals to the window dresser and the product goes into the window because it fits into some color scheme, is brilliant enough to attract in itself, or because of its beauty.

Uneeda Biscuit on the counter or shelf will often be packed with the red end label showing, because of the lack of color in the main package. Sunshine Soda Crackers, on the other hand, will be in continuous display on shelves, counters, and windows because of the brilliant red label. In its early days Shredded Wheat was in a nondescript, colorless-looking package. Then the sales promotion department evidently realized that they were getting no display. They began to use color, first in the strawberries on the carton, and from a back-shelf position the package gradually came to the front and is often seen in prominent display.

Color attracts the customer's eye and it is estimated that 75 per cent of buying is done through the eye. It also has its advantages in advertising, for a colorful package can be reproduced in the color section of a magazine exactly as it appears in the store, making the "hook-up" a strong one. Children are attracted by color and any package that is bought by children should have brilliant coloring, preferably the primary colors such as red and yellow. Green is a color to avoid on food products. It does not seem to appeal to the buying public. This applies especially to the packaging of confectionery.

The Carton. Considerations of economy are increasing the use of the carton as rapidly as it is developed for new possibilities. Milk is now being sold in cartons. Oysters are delivered in cartons. Biscuits in bulk are sold to the dealer in cartons instead of tin cans. As the carton becomes thoroughly waterproof, without doubt other merchandise will make its appearance in this kind of package because of the economy.

Sales promotion departments will do well to keep in continuous touch with progress in carton making which has gone far since the first introduction of the moisture and dust proof package.

The Insert. This is a form of advertising that is often neglected, and yet it is an opportunity for the manufacturer to shake hands with the consumer at the time when the product has passed into the consumer's possession. A word of explanation or commendation at this time often increases the satisfaction of the purchaser.

Such inserts can give recipes, instructions, a sales story regarding the product, testimonials from satisfied users, tests that may have been made by laboratories, colleges, or other organizations, construction features peculiar to the product, or questions and answers regarding the contents.

Loose Wiles Biscuit Company some time ago placed in each package of biscuit a paper doll, each package carrying a different kind of dress for the doll up to twelve in number, so that the owner of a doll by buying packages of Sunshine Biscuit could obtain a wardrobe of twelve different dresses. The company advertising informed the public that the doll and the dresses were in the packages and, of course, many children insisted on continuous buying, at least until they had obtained the complete wardrobe for the doll.

The Counter-display Carton. There was a time when the carton in which packages were delivered to the dealer was thrown away when the packages were placed on the shelf. Now the carton often becomes a counter-display fixture for the product, making it possible for the dealer to show the contents to the best advantage.

Many cartons have been patented in the last few years, notably those for Life Savers, chewing gum, toilet articles, Cannon towels, and many kinds of novelties.

Many of these counter display cartons are in brilliant colors and call attention to an article which otherwise would be lost among the multitude of items in the average store. The number of packages in the carton is usually a dozen and in many cases this prevents orders for "broken dozens" where the dealer is buying "from hand to mouth." Where the product is too large for counter display, a great deal of ingenuity has been put into its preparation for floor display.

This form of display offers an opportunity for the manufacturer to print on the back of the carton as it is set up a story in regard to the product offered for sale which can be read by the clerk serving the customer and used as a sales talk to the customer. The message should be printed so that it comes natural eye height to the clerk as the product is set up on the counter of the dealer.

Method of Packing Consumer Assortment. The sales promotion department very quickly becomes acquainted with the right kind of assortment. An assortment can be made attractive to a customer, as is evidenced by Whitman's Sampler of chocolates, the colors in a box of handkerchiefs, the size in a box of hooks and eyes, the colors in a make-up box, the surprise assortment of biscuits, and the package of Pinaud's lotions and toilet waters.

Such assortments must be worked out with a full knowledge of conditions in the trade, otherwise they may block sales and create dissatisfaction on

the part of customers. It is well to try out an assortment in a small way, taking a cross section of territory so that a fair test as to the wishes of the public can be obtained, before it is finally adopted.

Christmas or Holiday Packages. Formerly the box of candy or the box of stationery was the only thing that carried a holiday atmosphere. At the present time almost every package that goes direct to the consumer has been given a Christmas appeal through the decoration of the container or through advertising. In some cases this appeal has been inappropriately used but in other cases it has brought utility presents into style as holiday gifts to the advantage of the receiver. This is sometimes done to advantage through showing the use of the product under holiday conditions.

The Shipping Carton. The shipping carton should contain the number of packages that a dealer can purchase to advantage. It may be one dozen, two dozen, four dozen, even six dozen. This number should be ascertained by a study of conditions because a correct understanding of the needs of the market will avert the orders for broken packages which are made when the amount is not acceptable to the dealer.

The shipping carton, traveling by express or freight, standing on the sidewalk outside of the dealer's store, or even thrown on the dump, gives an opportunity to tell the story of the product it contained and advertise its use to the consumer. This space would be valuable if offered by an advertising company as poster advertising. It is available to the manufacturer at the cost of printing; notwithstanding this fact many cartons go into the trade blank on two or more sides.

The story can be short or long depending on the product; it can be varied as new cartons are made; it can show the product in use. The same advertiser who changes his copy on billboards and in street cars every thirty days entirely neglects the six sides of the shipping carton or runs the same copy year after year.

Service to Salesmen. It is in this phase of the work of a sales promotion department that its greatest opportunity is presented. The sales promotion manager stands between the sales manager and the advertising manager, interpreting for the benefit of the dealers the advertising offered by the advertising department and the sales plans presented by the sales department.

The sales promotion department should not try to teach the salesman how to do his work but should help him to get more business from the dealer. It is wise to consult freely with the salesmen as to conditions in the field, especially in the case of individual customers where there is trouble in getting the volume that is expected. On the other hand, the salesman can not stay in the dealer's store long enough to get all the information desired and surveys made by the sales promotion department, analyzed and given to him on specific accounts, will prove invaluable.

Market Survey. "A market survey is a positive study of potential consumption, competition, sales territory, sales methods, and advertising."

Whether this survey is secured from an organization specializing in the work, or made by the manufacturer's own organization, it should not be made by the salesmen who are responsible for the business and can not take an objective view point. If the survey is made by the sales promotion depart-

ment, it should not only include conditions in the field, but should study the books of the company. An analysis of the accounts with dealers will bring to the attention of the sales executive any violation or wrong emphasis of sales policy.

Research. A survey is of conditions as they exist at the time the survey is made, whereas research covers past, present, and future. Research defines the objective and manufacturers now realize the importance of careful research before offering anything new to the public. The old fashioned way was to manufacture a product, then turn it over to the sales department and tell them to sell it. This caused many slow moving articles to accumulate in the inventory because the manufacturer did not first find out what the consumer wanted.

Research has become practically a separate business. It is possible to conduct it under the direction of a sales promotion department, although an organization that will "let the chips fall where they may" usually can secure a clearer insight into the needs of the market.

Sales plans should also be created to fit conditions as they exist in the field, as shown by careful survey and research.

Sales Manual. The sales manual properly prepared is one of the greatest helps to the sales manager and salesmen that can be prepared. The method of building a sales manual has been described in the preceding chapter.

Sometimes a part of the sales manual and sometimes in separate form is a book setting forth the sales policies of the house. This "policy book" is divided so that matters which concern only the department heads are not included for the salesmen. This is best secured by the use of separate numbered bulletins. These can be taken out of the book or added and receipts can be returned by those who receive them so that the executive may know that each person has the information at hand. Such a book carefully prepared prevents arguments and secures clear understanding of the policies.

Another valuable aid to the salesman is the "sales idea digest" in which the best retailing ideas of dealers in all sales territories have been recorded from time to time as they are discovered by the salesmen. A "sales idea digest" in the hands of a salesman enables him to solve many problems that come to his attention and he finally gets the reputation with his dealers of being able to make a suggestion as to how they can improve their business under any conditions that may exist. A prize offered to dealers for ideas as to how best to sell the product will bring in good information for the sales department. The ideas for the digest should be simple in operation and positive in result, and should be recommended only when the conditions are the same as those under which the idea originated.

Advertising Portfolio. The material for the advertising portfolio is the product of the advertising department, but the sales promotion department can take over its preparation in the form and size best adapted to the salesman's use.

In the introduction of an advertising program the advertising portfolio is an important aid. It can be used together with samples, the sales talk of the salesmen and the preparation of supplementary dealer's service material so as to get the greatest possible value out of the advertising. Coordination

of the advertising with the sales program is a duty of the sales promotion department.

Pave Way for Salesman's Call. Advance cards vary according to the ideas of the salesman or of the sales promotion department. Some are dignified announcements, others use a cartoon that brings a smile, some show the salesman's photograph as a reminder. Such cards are sent to make an appointment or to suggest that the order be held until the salesman arrives on such and such a date.

This does not mean that a salesman will expect a dealer to hold back an order to his own house when the dealer needs the product. Arrangements are usually made for such orders to go through direct to the house, and credit to be given the salesman.

Where there is a reason for writing to the dealer that a salesman is on the way, such as to tell him of special bargains that the salesman will call to his attention on arrival, the double value is secured of notifying the dealer of the call and of making sure that the dealer knows of the special bargain. General information which is in the form of news of interest to the dealer can be included in such letter.

If it is known that the dealer has a complaint, it is a good plan for the letter to attempt to meet the difficulty so that the way will be open for the salesman to take up the subject on his arrival. This shows the desire of the sales organization to satisfy the dealer where it is possible.

The sales promotion department may have discovered a prospect on whom the salesman has never called. In this case the letter will be more explicit and outline in a direct way what the dealer can expect from the salesman when he calls. Help of this kind is always acceptable to the salesman. All salesmen dislike what is known as "cold-turkey canvass," that is, to approach a dealer without any introduction or previous call and attempt to get an order.

Writing to Dealers Missed by Salesmen. A dealer is complimented when he receives a letter from the house apologizing because the salesman was not able to visit him on his last trip.

The reason for skipping or missing a dealer should be given by the salesman and should be a valid reason, otherwise no letter should be written. If the letter is written it should include the story that would have been presented by the salesman to the dealer, particularly if it is a special sales proposition. After the salesman has seen the results from some of these letters, he will be very glad to supply the information that will give the letter a personal touch.

In every case a copy of such a letter should be mailed immediately to the salesman that he may know exactly what to take up when he calls on that dealer the next time.

Maintaining Contact with Dealers. Any constructive letter written to a dealer for a legitimate reason is helpful. Often a news item taken from a paper or magazine will give an excuse for writing a dealer. On a tip given by the salesman as to the size of the previous order a letter can be written calling attention to the necessity of keeping up stock and directly asking for an order. This would apply particularly where a line is fast moving and the

previous order has been small. Where the dealer did not buy, a good sales talk sent to him soon after the salesman has left the territory is sometimes helpful. It does not pay to carry on solicitation of this kind indefinitely and it should stop when a specific reason for the letter is lacking.

In these days of small-order buying, frequent contact with the dealer is necessary. The telephone, sometimes the telegraph, many times the catalogue, or a letter with a good sales talk will keep the line active in the dealer's store.

A salesman sometimes thinks that an item has gone out of style or has been superseded by a new product and forgets that there are dealers who have trade for the items longer than others. By watching each dealer's card the sales promotion department can detect such a customer and write a letter calling attention to the items that are older and perhaps forgotten by the salesman, and can thus maintain enough of a demand to reduce the factory inventory materially.

Letters of Welcome to New Dealers. When the president of the American Telephone and Telegraph Company takes the time to sign letters of welcome to new stockholders added to their list and letters of regret to stockholders who have been taken off their list, it seems reasonable to think that it would profit a business organization of almost any size to welcome a new dealer into the organization. A new dealer likes to feel that he has made contact with the house other than through the salesman. He likes to feel that he is a factor in the manufacturer's business and a letter from headquarters thanking him for an order and including in the letter some specific reference to the order, or to the conditions under which it was taken, is a personal message of value.

Handling Complaints from Dealers. All complaints should be answered carefully. No complaint is too small to receive the attention of the home office. Over a period of time the department will accumulate the best answers to dealers' complaints. In other words, complaints repeat themselves and the sales promotion department can maintain a book of best answers, used by correspondents in answering such letters. These answers should not be used in such a way as to give the appearance of a form letter. Humor should be avoided in these letters. There is danger that when the letter is received the recipient may not be in a frame of mind to appreciate the humor and it will then antagonize him.

Contests. James Maratta says of sales contests:

The trouble today is not with sales contests but rather with inexperienced sales managers and other executives who plunge an organization into a contest for no particular purpose and with no end in sight other than to pass out prizes. The value of prizes has nothing to do with the success or failure of a sales contest, for it is a proved fact that men will risk limb and life for the honor of leadership and snap their fingers at an increase in remuneration for a common service. Contests are the life blood of a wide-awake sales organization and, when planned with the painstaking detail given to merchandise and advertising programs, will result in immediate increase in business.

It is true that there is usually a reaction from a drive for sales, but there must be a drop in the curve after any peak in sales. The important factors

are the choice of a contest which fits the particular case, and a fair trial with good support. John M. Kumler has given some fundamentals for sales contests from which we quote:

1. If merchandise prizes are used, preference should be given to standard, nationally known, and wanted goods.

2. The best prize combination is a cash grand prize and attractive merchandise awards for all.

3. A prize given with each unit sold is not so effective as a larger prize achieved by the sale of a number of units.

4. A contest that appeals to the strong salesmen only is not worth while.

5. The contestants should select their own prizes. This is made possible by offering a large variety of prizes.

6. Bulletins and letters should be as personal as possible. Men respond more quickly to the encouragement and the personality of the sales manager than to general material that is not definitely connected with the plan.

7. The rules of the contest once formulated must not be changed for any individual salesman.

8. A personal message to the salesman's family at the beginning of the contest enlists their sympathy and influence.

9. If a contest is used for jobbers and wholesalers, it is best to confine it to the salesmen of such houses.

10. Acknowledgement and thanks should be given to a prize winner in addition to the prize.

11. There should be as little delay as possible in giving the awards.

12. It is unwise to start a contest just to be doing something. A real purpose is essential.

13. Some successful contests have been run without prizes.

14. A sales contest should be run to get sales—not for the purpose of determining the best salesman.

15. A sales contest that appeals only to individuals will never achieve as great results as one which appeals to groups.

16. A sales contest is fundamentally unsound if it offers opportunity for the contestant to quit at any time. It should be so constructed as practically to force the contestants to continue to the end.

17. While rewards for new business through new accounts should be larger and of more value because of future possibilities, no contest should be run in which the contestants are so eager for new accounts that they neglect old customers.

18. In staging a contest consideration must be given the fact that a certain amount of business would normally result during this period providing no contest was held. Therefore, additional costs for business resulting from a contest must be borne by the new or additional business secured.

19. A dealers' contest should be supplemented by direct mail matter in such a way that new prospects may be discovered and turned over to the salesmen.

Some of the reasons why sales contests have been carried on are:

1. To acquaint the men with one another as the members of departments within the organization are acquainted with their fellows.

2. To provide a healthy spirit of rivalry among scattered men, something like the rivalry which may exist between skilled workmen in the factory.

3. To stimulate sales in a dull period of the year.

4. To put additional emphasis on certain objectives in selling, for example, through prizes for the greatest number of new customers, or greatest excess over a predetermined quota.

5. To show the majority of the men what can be done and is being done by the most effective salesmen on the force.

6. To provide for a drive to introduce new items that have been added to the line.

7. To provide interesting printed material which will serve to keep the house in regular contact with the men on the road.

8. To provide that the names and achievements of salesmen are put in a form which the executives see regularly, thus insuring recognition from the house as well as from the sales manager.

9. To replace artificial "pep" messages with something more substantial in the way of recognition for good work.

10. Sometimes to get friend wife into the picture—where a salesman's house organ is mailed to his house and she sees it and discovers that her man is either a hero or should be urged to become one.

11. To stimulate a whole branch office that may be lagging.

12. To show the "stars" that the young fellows are coming along fast.

13. To make new acquisitions to the sales force properly modest by keeping constantly before them the achievements of the high men.

There are many kinds of contests. We shall mention a few to give an idea of the possibilities. The lobster-and-bean contest explains itself. It is on a team basis, one matched against the other, both teams sitting down to dinner together at the close of the contest, the winners eating lobster and the losers eating baked beans. The automobile race is a contest in which progress in sales is represented and dramatized by toy automobiles advancing across a big map in the office. This map is reproduced by photographs which are forwarded to the sales force showing the positions of the racers each day.

A satisfactory contest, and one that usually produces the maximum of effort, is one where the wife, sweetheart, or mother is the "sales manager" of the individual salesman. All information goes to the lady. All of the prizes are such as will appeal to her and are given to her if her salesman wins. A contest that is usually pleasing to the organization is the vacation club contest where the prizes are a week's vacation, such as a week's vacation and a complete outfit of wearing apparel and all expenses paid; an aeroplane trip to Atlantic City; a steamer trip to Virginia Beach; an ocean cruise to Boston. These trips can be made as short or as long, as cheap or expensive as the contest warrants.

The president's birthday or the president's return from a vacation or the anniversary of the founding of the business will furnish sufficient occasion for a contest which can be made for prizes or for the pleasure of doing something for the good of the business. Often the best prize is a list of the winners framed and placed in the president's office.

The thermometer contest where the temperature goes up or down in accordance with sales can be made spectacular and interesting.

The General Electric Company put on a circus contest which increased the sales of the electric refrigeration department 30 per cent. It was for a \$20,000,000 quota established for the period between Oct. 1 and Dec. 9. Prior to the campaign men with some knowledge of circus activities were dispatched to visit the leading circuses. They interviewed outstanding stars and con-

sulted with circus executives, they spent considerable time in watching all the activities from the time a circus arrives in town during the gray hours of early morning until its trains are loaded to start on the way to the next town. All this was done to get authoritative material that would provide spectacular sales parallels and general data for the promotion of the sales contest. The layout men, copy men, convention plan men, and others were required to gather first-hand material by visiting the circuses and in some cases by actually living with the circuses. Therefore, when the campaign was launched with all its color, brilliance, and glamour it is small wonder that over 17,000 registrations were received from salesmen as compared with the 10,000 of the previous year in a similar sales contest. A different letterhead had been prepared for each mailing in the campaign. One of the things most essential to the success of a campaign such as this is variety, distinctiveness, and attractiveness in the letterheads used for the messages prepared. The promoters of this campaign are quoted as saying,

In the light of the campaign success we consider it highly desirable to select an unusual theme and promote it in the most colorful and impressive manner when there is need for stimulating sales at a time when business is hard to get.

A contest that arouses a great deal of interest is a Stock Market contest. The phraseology is readily adaptable and every salesman gets a thrill as he watches his stock rise or fall to new highs and lows, each time the tickers tick. The National Lamp Works of the General Electric Company tried this contest very successfully. This was for the development of business rather than the obtaining of new accounts. The result was "nearly \$500,000 increase in sales of 3,730 retail agents over 9,000,000 square feet of factory, store, and office space relighted to a modern standard." Each jobber salesman was asked to select at least five and not more than fifteen of his most promising agents to serve as his "common stock" during the period of the contest. On these agents he was to concentrate during the six months period to help them show an increase in lamp sales as compared to their records for a similar period the preceding year. The combined six-months sales of his group of selected agents was termed the par value of the salesman's "stock" and served as his quota. This was recorded by the month and as sales were reported month by month during the contest, his stock quotation was published in the score called "the ticker." It was supported by the use of stock certificates and all of the language of the Street.

The Frigidaire and Addressograph companies have also worked the Stock Market contest most successfully. The quotation board in the case of the Frigidaire Company was set up in each district office and a ticker tape on which quotations were typed in regular approved form. The market reports and letters to the salesmen were all in the language of the stock market. In the case of the Addressograph Company, the only ticker used was a clock which was referred to as being "the only ticker that counts in big dividend contests."

There are other special sales plans which do not use the contest idea, such as selling a ton of a product. This was successfully operated by the Sunshine Biscuit Company by selling the dealer a ton of biscuits which he was to sell

within a period of one week. It was supported by a parade through the town, window displays, and advertising. Another sales plan is the "carload" plan, A carload of the product is to be sold by the dealer in a week's time. "Sales weeks," which are operated by many companies involve concentration on a product for a week together with the use of types of publicity and advertising.

As a rule a contest or a big sale arouses the interest of the dealers. They like to get into the game with the salesmen and often will increase their orders where it helps a salesman to win a prize.

Service to Dealers. The service to dealers by a manufacturer through the sales promotion department is usually by means of direct mail. From an article written by T. W. Combs, Sr., we have selected the following checking points for the use of direct mail:

1. Was the idea of sufficient interest and value to justify its development into a direct mail message?
2. Did the copy clearly and completely explain the benefit your proposition offered the reader?
3. Was the message written in words that you or your salesmen or the dealer or the dealer's clerk could use easily in conversation?
4. Were all of the sales points in the opening paragraph with the result that no one of them was clearly expressed?
5. Was the entire history of the business, of the product and of its accomplishments given in one letter?
6. Was the message clear cut, fact giving, unmistakable in its meaning?
7. Was the copy read aloud to some disinterested person so that there would be a chance to correct any wording that gave a wrong impression?
8. Was there anything in the message that could be disputed, that might invite controversy or argument, anything that would have to be defended or excused?
9. Was an attempt made to copy someone else's style in writing the story?
10. Was the story all about "our product and us" instead of "you and your interest?"
11. If the copy was intended to persuade people to go somewhere and buy something, did it tell them where and how to get it?
12. What basis was there for thinking that the copy was satisfactory?
13. Was the attempt to please the readers to whom the mailing piece was addressed or was it to suit one or more of the executives?
14. Was the mailing piece sufficiently illustrated with new drawings or was money saved by the use of old drawings that were "good enough"?
15. Were the illustrations so surrounded by type matter that it was like looking over the heads of a crowd in the effort to see them, or did they have the proper setting in plenty of surrounding white space?
16. In the direct mail furnished the dealer or jobbers for them to distribute, particularly envelopes, inserts or stuffers, is everything sacrificed for low cost? Does the copy which is supposed to be serving their interests mention their names only with an imprint that is hardly noticeable? If so, that is probably the reason why they do not use the material.

One of the most important things in service to dealers is that the mailing list should be active. It should be checked and rechecked continuously in order to be sure that it is up to date. Where the lists are bought from firms

that offer them for sale, care should be taken that they are purchased from a reliable source. In case tax lists, auto registration lists, lists of property owners, telephone lists, etc., may be used, the sales promotion department can secure these for itself.

In any use of direct mail methods it is well to remember that nothing will get the support of the salesman for the sales promotion department more completely than the knowledge that whatever business comes from his territory by mail will be credited to him and that he will receive the commission thereon.

Broadsides to Dealers. The broadside is usually the introduction of an advertising campaign or special sale. The size gives them the name of broadside. They are used to attract the dealer's attention in the hope that a quick order will be placed. To make this easy, ingenious devices for inserting the order blank, return envelope and sometimes stamped return envelopes are enclosed. The return envelopes on which the postage is paid on their receipt, are now used to good advantage. Broadsides are usually well filled with pictures of the product in action or use.

Double Post Card. The double post card is used many times as a reminder of a product the dealer may have forgotten on his previous order, an assortment of particular value, or a sale at a special price. Some firms keep careful check on the orders and know about the length of time within which the product should be sold. When the supply is supposed to be low, a double post card is sent to the dealer reminding him to stock up.

House Organ for Dealers. One of the values of the house organ to dealers is that it makes the dealer feel that he has registered with the house as a customer and that he does not exist simply in the mind of the salesman.

The house organ to dealers has great possibilities, but its value is often sacrificed through lack of understanding on the part of the sales promotion department as to the material that should be included. It is not a place to put the pictures of all the officers of the organization, of the factories, and branch houses, and to talk continuously about the product and how wonderfully it is manufactured. The dealer who receives the house organ wants to read what the company has to offer for his benefit, how he is going to sell more of the product at a profit, how to interest his customers in buying more, and what other dealers are doing in various parts of the country.

Pictures of the product in action or in use, which will give him new ideas as to how to present it; arrangements of stores windows, or delivery trucks; in fact, anything that has to do with his own store is of interest to him. If there is something special to offer it should be presented in such a way as to get his interest not in *buying the product* but in *selling at a profit*. Current news from dealers in all parts of the field, local information of interest, photographs of stores with names and addresses, some testimonials when they are true—all these are worth using.

It is possible for the company itself to print a satisfactory house organ. In other cases, men that specialize in this work put together the material, which often includes research information of benefit to the dealer. It has been found best not to use humor except in the form of cartoons and these must be so drawn as not in any way to ridicule the product or the seller. Color

may be used to advantage. The copy should be written in the language of the dealer, not of the factory or the office. The person who writes it should be in close contact with the dealer, with his method of selling, and his problems.

It is better to have a house organ of four pages which really says something than of sixteen pages with material very evidently supplied to fill the space.

At times a special edition of the house organ can be sent the consumer to advantage. In the case of such products as a lighting plant, an office appliance or a tractor, a selected mailing list of consumers prepared by the dealer can be used to advantage. In that case, the house organ should be prepared with the consumer as well as the dealer in mind.

Special Mail Campaign. A special mail campaign should not conflict with the regular operations of the sales department. At no time should an offer be made by mail that is not available for the sales force to make directly to customers. Where the campaign is run in territory covered by a salesman, he should receive credit for the business obtained.

The care and completeness with which a mail campaign is planned and the value of what it offers make for its success or failure. The right kind of mailing list carefully checked is essential. Color and illustrations that show the product in use or action, with enough text to explain the use, and a clear price are elements in a successful plan.

A special mail campaign can be used to open new territory, open new accounts that have not been covered by the salesmen and to open accounts in small towns where the expense of a salesman's call is too great considering the amount of available business. The special mail campaign can be used to good advantage for special merchandise. This may be seasonal, a new assortment, or an offer at an advantageous price. No special mail campaign should ever be put out, however, without something in it of specific value to the person addressed. To get out special mail campaigns at regular intervals regardless of what the message may be, hurts rather than helps a business; but if the offer is advantageous to the dealer, the frequency of issue does not decrease its effectiveness.

A service to dealers that may be classified as a special mail campaign is that of a series of numbered bulletins to dealers. They are numbered so that the dealer can be sure he is getting each one, and each bulletin contains one item of interest to the dealer. This may be an explanation of a product or it may be a sales argument, but when the dealer has accumulated a number of these bulletins, he has information that will be helpful to him in selling the merchandise. They should be sent when there is a real message, not at regular intervals and just because the time has arrived.

A mail campaign should be keyed to the audience to be reached. It is not necessary that such a campaign be national in its scope. A certain section of the country may have a mail campaign of its own, and specifically written for that particular section, it is of greater value than if it were written in a general way for the whole country.

A new use for a product is a good basis for a mail campaign. The dealer is interested in the use of the product, because he can pass the idea on to the consumer. For example, the idea that an alarm clock can be used to advan-

tage in the kitchen sold many more alarm clocks. A woman can put a cake in the oven and know that in a certain number of minutes it will have to be taken out, set her alarm clock, and go about her work in some other part of the house, relying on the alarm clock to advise her when to pay attention to the cake. This means less burnt cake and more sales of alarm clocks.

Suggestions to the dealer as to what kind of copy to put in his own advertising are welcomed, if written from the consumer's viewpoint and not too exclusively from that of the manufacturer.

Dealers' Meetings. Group meetings of dealers, all interested in the same distribution problems, are profitable. Where the product is technical like a tractor, motor car, or adding machine, moving picture films can be used to great advantage, supplemented with slides to bring out the detail, giving the dealers a comprehensive understanding of the make-up of the product, its strength and what it will accomplish.

The meetings should be friendly and social as well as instructive. If they can be held in the factory or in a branch house, the dealer will feel more at home from the proximity of products with which he is familiar and will unbend more quickly. The talk should be simple and direct and opportunity given dealers to ask serious questions about the conduct of their business. Most dealers dislike being preached at, but they will take as much as you can give them when it is done with the right attitude. The salesmen can be of great value at a dealers meeting of this kind, particularly if it comprises the men from more than one district.

A very definite program should be prepared showing that thought has been given in advance. If plenty of the product is around, the dealer will take more time to examine it than he will in his own office or store where he is constantly interrupted by customers. A strictly business meeting goes over with the dealers just as satisfactorily as one that has a great deal of entertainment. One thing that does help is a bit to eat, whether it is a sandwich or a more elaborate menu.

Propositions to Dealers. A proposition to a dealer must be of real value, otherwise, it is better not to send it out. It must carry through to the point where money is made for the dealer.

Dealer Service Book. This book can be made a valuable help to the salesmen. Aside from the material offered for sale, it should contain useful photographs such as those of window displays, interiors of stores or delivery trucks, clippings from the newspapers pertaining to matters of interest to the dealer about the product you are selling, sample orders giving an idea of the various dealers who are interested and in what quantity they stock the goods, and samples of the advertising that has been done by dealers. The dealer is always interested in what the other fellow is doing and a clipping from some newspaper, showing an advertisement with data from the dealer as to what results it brought, is always good reading. Statistics should have their place in the service book but should be carefully selected so that they mean something to the dealer.

The salesman should be able to use the service book while conversing with the dealer and keep his place in it so that he can turn the page when the time arrives to illustrate the point. The dealer will hesitate about sitting down

and looking through a whole book of material, but can be interested in it if the salesman uses it to illustrate his talk with pictures and figures.

One of these books that has been used successfully sold over a million dollars worth of dealer's service material in one year. No profit should be made from dealer service material sold; but the sale of the material, at cost, will make it of greater value to the retailer than if he had it given to him. Very few people appreciate what is given to them, but if they have paid for it they use it and get the best out of it.

This book should be displayed by the salesman after the order for the product has been taken.

Free Deals. Like many other subjects this one has two sides. Some manufacturers believe that free deals help them to sell merchandise; others offer deals in order to bring out a second product, selling the first at a sacrifice to introduce the second. Some feel that a free deal "loads" a dealer; they also fear that when the dealer becomes accustomed to getting free deals, he will wait for them and thus the manufacturer will always have to sell his merchandise at a cut in price. The dealers themselves also realize that merchandise purchased in quantity, in order to take advantage of a deal, ties up capital.

Certain leading companies use deals and claim that they are to the advantage of the business. The caution must be given, however, that an analysis of the individual business should be made very carefully before a free deal is offered. If the decision is to use it, then regularly every three, six, or nine months a record should be made of exactly the amount of money that has been given away through free deals. This money comes out of net profit and for every five per cent cut in price, it takes a 25 per cent increase in business to break even. An analysis of the actual expense of a free deal will often change the manufacturer's mind.

A free deal should be differentiated from an introductory deal made to allow the possibility of sampling the product. The latter, however, is open to the danger that the dealer will put the extra supply on his shelf to sell for more profit instead of giving it to his customers so that they may become acquainted with the product.

When free goods are supplied by the wholesaler four methods have been adopted:

1. The wholesaler is furnished the free goods and instructed to pass them on.
2. The wholesaler supplies the free goods by breaking cartons of his own stock and charging them back to the manufacturer at his price.
3. The wholesaler does the same but charges to the manufacturer at cost prices.
4. The wholesaler does the same, then notifies the manufacturer and receives a replacement of equivalent goods.

Where the manufacturer supplies the free goods directly to the dealer, four plans are used:

1. The entire order including the free goods is shipped directly by the manufacturer to the retailer but is billed through the wholesaler.
2. The manufacturer ships the free goods directly to the retailer upon receiving from the retailer the paid invoice.

3. The manufacturer ships the free goods directly to the retailer upon receipt of boxes from the wholesaler.

4. The manufacturer ships the free goods directly to the retailer upon receipt of coupons included in the carton.

One manufacturer says: "The free deal is our most powerful weapon with retailers. They know it is the way they can get the best prices." On the other hand, it is generally conceded that the principle of free deals is not economically sound. A straight discount of an amount equal to the free goods would be more sensible. The word "free," however, beguiles the dealer and at the same time protects the manufacturer from returned goods.

Assortments. We have already discussed the assortment in the individual package and in the carton that goes to the consumer. There is another type of assortment, namely, an order for the dealer packed in one carton including several different kinds of merchandise each in proportion to the average sale of the average dealer. In this way original containers are shipped without broken packages and at the same time the dealer receives an assortment. Only by careful study of stores in various districts can an assortment be made that will be satisfactory to the dealer. If it is not carefully prepared, he becomes overstocked on certain items and there is either a return claim to the manufacturer or an overstocked and unsatisfactory condition for the dealer.

Window-display Plans. Window-display plans are presented for consideration so as to avoid the waste that usually follows an indiscriminate delivery of window-display material to all dealers regardless of their window space. Suggestions as to how windows can be made valuable are sent out to the dealer as a service. An example is that old time plan, always good, always sure of attracting a crowd, the device of pasting a sheet of plain paper across the window, cutting a hole at eye height, and decorating the window with the product on which you want the customers' attention concentrated. This plan is so old that it probably came over with Noah, but it still works. Human nature is the same today as it was the day the first man went up to the window to look through the peep hole.

There is a type of window that always draws a crowd, prepared by an offer on the part of a big department store or some dealer's store that has a large window, to the little girls of the town or city. On a certain week there is to be a doll exhibit and they are invited to bring their favorite dolls, each to be marked with the name of the doll and the name of the mother and placed in the window. Prizes are offered for the best selection considering beauty, novelty, etc. It is easy to figure what a tremendous attraction that window is. Fathers and mothers, uncles and aunts, have to come down to see the exhibition and, of course, while there, they buy something that they have needed.

A telegraph instrument can be located in a big window with merchandise to be advertised also placed on display. The operator sitting at the telegraph instrument which ticks in the regular way, writes a telegram and holds it up to the window. This tells the crowd on the outside something about the merchandise available. If a number of telegrams are left around the window or pasted up on it, people will stop and read them and get the message about the merchandise.

To take merchandise from other stores and give them credit in the display is sometimes good advertising. For instance, if there is a big charity ball to take place in the city and the dealer is in the shoe business, he can borrow a wax figure dressed in a ball gown and add the shoes to match. The dealer in dresses returns the compliment by displaying the shoes and giving credit in his window. A radio can be added to each to supply the dance music.

A contest among dealers in different parts of the country supported by photographs and prizes will give good advertising to the merchandise and satisfaction to the men responsible for decorating the various windows.

A well-lighted window is one of the best advertisements a dealer can have.

The sale of window space by some of the larger department stores and drug stores is a problem which has to be treated on its individual merits in each case. As a rule unless the manufacturer is willing to purchase these large windows and supply enough merchandise to fill them, the discretion of the window trimmer of the store will prevail.

If the dealer can be persuaded to order window material through the dealer's service book or through some advance bulletin from the sales promotion department, he is much more likely to use it, than if it is shipped to him and he is merely advised that it is on the way. Some companies sign up their dealers for window displays over a period of time; others sell a monthly service at so much on a yearly contract and a change of display is sent to the store purchasing, once each month.

Demonstration Plans. Many stores will allow a demonstrator to come in for a certain length of time at the expense of the manufacturer. Other demonstrations may be made by the regular clerks in the store although in most cases the manufacturer contributes something towards the expense. In some cases a certain amount of product is given to the dealer with the understanding that he will demonstrate at his own expense. A demonstration plan is not the same thing as a subsidized department. In the latter a permanent display and sale of the product is conducted at the expense of the manufacturer with the dealer taking a certain percentage of the sales.

Food products are often demonstrated by a dietician. Gas and electric stoves, washing machines, and dish washing machines are demonstrated by showing what they will accomplish. A demonstration is often used in introducing a new product. Dealers do not care to buy stock until some evidence of demand for the goods has been demonstrated. Window demonstration is a type frequently used. This is used for exercisers of all kinds, hair restorers and crimpers, knife sharpeners, suspenders and many other products that lend themselves to the method.

The Booklet Plan. The use of booklets is entirely separate from the plan for a house organ. The booklets are usually devoted entirely to explanations of the individual products. An example of this is the recipe book featuring the product. Booklets are often prepared in connection with machines that require considerable explanation. In other cases such as that of scales for bath room use, the booklets give reasons for the use of the product, as for example the importance of retaining the proper weight.

In the case of a new product like Tish the booklet is made up almost entirely of pictures each picture showing a different use for the product. Booklets

are used for a family of products, to get them all before the public at the same time. As a rule these booklets are sent direct to the dealer or are mailed by the manufacturer to a list of consumers supplied by the dealer. Booklets often carry the imprint of the local dealer so that when the consumer becomes interested he will know where to purchase.

The number of these booklets supplied will depend upon the size of the order, although at times the manufacturer is glad to supply them to the extent that they can be used to advantage. It is usually wise to limit the number to prevent waste. The dealer is more likely to prize them and use them to advantage if the supply is not unlimited.

Sales Plan. When a definite sales plan is supplied to the dealers by the salesmen, it is well to present this in advance to all of the dealers by mail. This allows the dealer to think over the proposition and become interested in it before the salesman calls. It also helps the salesman not to forget the sales plan. Other sales plans that are not considered of so much importance can be presented entirely by mail. Whenever they are thus offered, a duplicate letter should be sent to the salesman on the territory. Samples of such plans are the offering of a flag to every purchaser two or three days prior to the Fourth of July or Memorial Day; a \$10 prize to any customer who will make the best suggestion in one week, for the improvement of the dealer's window; a coupon in each pair of shoes good for an extra pair of shoe laces when presented with the name and address, thereby building a good mailing list for the dealer; concentration by all of the clerks in the store on one article each day, this article to be offered to every customer; a small bag of marbles to be placed in the pocket of each pair of boy's overalls. An appeal that can be made to children, that is adaptable to the merchandise offered for sale, is usually good advertising.

An intelligent use of the telephone by clerks can be outlined to the advantage of the average dealer. The best clerk is put on the telephone calling Mrs. Brown at 9:05, Mrs. Smith at 9:15 and so on each day. The consumer becomes accustomed to these calls and to the voice of the clerk and has confidence that he will send a product as represented. This work can be picked up at odd times so that it does not interfere with attention to the customers in the store. It can not be entrusted to a mediocre clerk; in a number of stores the proprietor is the one who handles the telephone trade.

Simple selling plans of this kind show interest on the part of the manufacturer in the success of the dealer. After they have been sent out they can become a part of the sales idea digest for the use of new dealers.

Special Price Sale. Circumstances arise that warrant a quick presentation of a special price to the trade and this service by mail immediately presents it to the entire trade. If one waited until the salesman made each call, the timely value of the price might have disappeared.

It is not wise to offer too many of these special prices. It will interfere with regular sales by the salesman.

Special Price Items. When an item is becoming obsolete and it is the desire of the factory to reduce inventory in order to make way for some new product, a special price on this particular item may be offered to the entire trade. It must be special or it is of no value.

Standard Sales Talk. Many salesmen object to making a sales presentation in words other than their own. Therefore in some organizations every salesman has a different way of presenting the sales story about the product he offers. The sales promotion department can be helpful by accumulating all of these various methods of presenting the same product including the method recommended by the executive organization. Out of the whole collection the one best way to sell the piece of merchandise will appear. There is only one. If the concensus of opinion presents a standard method as the one best way, it has been proved that if every salesman uses this method a greater volume of business will be done than where the presentation is left to each salesman's individuality. By no means does this mean parrot work. The salesmen who object to the plan should be reminded that they have seen many impersonations of Hamlet on the stage, but probably no actor has ever interpreted this great character in exactly the same way or left the same impression upon the audience. He was repeating, not his own words, but the words of Shakespeare, but the interpretation to the minds of his audience was his own. So the salesman can take the one best way to sell, and put back of it his interpretation of what those words mean by language, method or gesture, adapting it to the intelligence and attitude of the individual buyer's mind. Salesmen, new or old, will appreciate the value of such a presentation once they get the spirit of it and use it.

The National Cash Register Company is an exponent of this plan. They have probably used it more successfully than any other company and they insist that every salesman shall learn the one best way to sell a cash register.

Display. Under this subject we shall discuss the material for display.

Window Display. The importance of this topic has already been indicated in the discussion of window-display plans. According to Davis Meyer of the United Cigar Stores Company two thirds of the entire rental of the store is placed on the window.

The advertising manager of Eberhard Faber Pencil Company sent out a questionnaire from the answers to which the following summary was made.

1. One general window display designed for an average sized window is satisfactory. It is not necessary to have three displays made to fit large, medium, and small windows respectively.
2. The largest-sized piece generally used for window display should be not larger than approximately twenty-four by thirty-six inches.
3. The most popular display is a large centerpiece with wings on each side together with several smaller easel-backed cards.
4. A window display featuring several well-known products made by the manufacturer is preferred to one advertising only a single product.
5. A manufacturer can advantageously furnish display sufficient for a complete window about twice a year.
6. Modernistic art work is desirable. This is the unanimous verdict of both jobbers and dealers.
7. A considerable number of jobbers will send out to their dealer-customers at least one display a year provided these displays are sent to them packed complete in individual cartons ready for convenient reshipment.

8. Business reply post cards can profitably be furnished to jobbers' salesmen so that they can mail these to the manufacturer giving the names and addresses of customers who will use the manufacturer's window display.

9. Paper streamers approximately twelve by thirty-eight inches are acceptable for pasting on windows.

10. Enlarged reproductions of timely advertisements which are being run in national publications, may be used for window display, but quite a large minority of dealers are not enthusiastic about this form of advertising.

11. It is not necessary to have window displays of a style exactly like that of the advertising used in publications.

12. The elements of novelty and of human interest seem to be of major importance.

It is always advisable for the manufacturer to set up an experimental window of average size in his factory or office and experiment therewith before even preliminary suggestions are sent out.

A window display that will break up into units which can be used on counters or shelves will secure a longer period of use. On the back of every display should appear a diagram showing exactly how to set it up, even though it may be very simple of construction. There is always an advantage in the use of action in any display where it is possible. Another feature that will bear emphasis is the utility of the material. If the product itself can be made part of the display or card, it enhances its value. Specifications as to paper and color of ink are important, for a warped or faded window display is a detriment. All material should have the form number and date so that it can be easily indexed, inventoried, and ordered.

The window is the point of contact with the consumer. It says, "Come on in; this is the article you heard advertised over the radio, saw in the newspaper or magazine, on the billboard, or in the street car. I have it for sale."

Snipes. This is not a very dignified type of advertising and one that is rapidly fading out of use. A snipe is usually a poster of one-sheet size and is pasted on fences, barns, or wherever the advertiser thinks he can "get away with it." Stricter laws in regard to this kind of work are now being enacted and its use is decreasing.

News Posters. This is a service used by some dealers to attract attention to their windows. It is supplied by houses equipped for this purpose and gives photographs of news events all over the country with a short explanation under each picture. Some dealers who do not care to use this service prepare their own photographs of local events, parades, accidents, fires, etc. Many people will stop to look at a picture, particularly if it is pasted irregularly on a window. But it is, of course, only good as an attention-getting device.

Giant Advertisements. The value of these is to emphasize the newspaper and magazine advertising by enlargement, making the tie-up a little closer between advertising and the point of sale. It is of value from this point of view, but usually a more valuable display can be planned for a window than a reproduction of this kind. In fact, it would be fully as useful to fold the magazine or newspaper and display it in the window showing the original rather than the giant advertisement in itself.

It is a very simple and inexpensive process, however, and there are occasions where it can be used to advantage.

Enlargement of Advertisement with Broadside. This is another case of the giant advertisement and usually attracts less attention than the original work. A broadside is of value because it goes directly into the hands of the dealer or consumer and is not particularly adapted to display work.

Store Arrangements. This is a subject that must be approached with each dealer in a guarded manner. The sales promotion department must be careful that their knowledge is accurate and that the recommendation will work in that particular store. The voluntary chains have taken this up to a great extent and are successfully adapting to the individual store advantages that have been demonstrated by the regular chain stores. The work includes rearrangement of counters, reducing the number of counters, rearrangement of shelves, improvement of the lighting fixtures, facilities for the use of self service, and other points in securing a modern up-to-date store. Good, clean paint adds one of the greatest values. The sales promotion department should make a study which will include many photographs of satisfactory stores, and equip themselves with information that will immediately be recognized by the dealer as practical and workable.

The dealer should remember that the first fifteen feet of counter and shelf room in his store are the most valuable and also that the space on the right will sell more goods than the corresponding space on the left. He should bring his profitable merchandise to the front and let the customer and the clerk walk to the rear of the store for the every day products that people will ask for whether they see or not.

Counter Display Fixtures. This comprises fixtures for the display of neckties, collars, suits, candy, vegetables, cigars, etc. Counter display fixtures can very well be included in the dealer's service book and sold to the dealer at wholesale price. The fixtures should be attractive, sturdy, and inexpensive. This does not include the counters themselves because they are a part of the equipment of the store.

Store Display Fixtures. A store display fixture that is attractive enough to appear in the advertising of a product by the manufacturer will be used by the dealer to tie up the advertising with the goods at the point of sale. The outstanding example of this is the Sunshine Biscuit rack which for nearly a year appeared in the color advertising and consequently had a prominent display in every store.

In the case of the store display fixture referred to, the dealer paid for it and valued it accordingly. Sometimes a fixture is sold with a small assortment but given away with a large assortment. In some cases the dealer is allowed to keep it so long as he remains a customer of the particular manufacturer and uses the fixture for the display of his products. Sometimes the cost is rebated in accordance with purchases by the dealer. This fixture should be displayed in the dealers' service book.

Electric signs are coming into use quite rapidly for franchised dealers. In some cases the manufacturer pays liberally toward the cost of the sign so long as it remains in front of the dealer's store, while the dealer pays for the space, electric current and maintenance. The Neon Company have a deal whereby they will arrange for payment for the sign over a period of three years, on monthly payments.

Agency signs in windows vary from high grade bronze to ordinary tin and sometimes paper. Such a sign tells the passing public that the store is the agent for a certain manufacturer's products. Most dealers are glad to display a manufacturer's sign of this kind where they have the agency.

Monthly Dealer Service. This usually comprises a window trim once each month or less often, supplied on a yearly contract basis and prepared in accordance with the seasons or the demands of the public. In some cases the manufacturer makes the contract and supplies the service at no charge; in other cases a nominal sum is paid for the displays. They can be sold to the dealer and when sold are used by the dealer, where in many cases displays that are shipped free to the dealer are never opened or occupy preferred positions in his cellar. The quality and appearance of the display is a big factor but in case a dealer signs up for a monthly display, he will usually put it in his window.

Things to Do for the Dealer. At best it is only possible to list a few of these things and the sales promotion department can easily add to the list. Things that are done for a dealer must be of a constructive nature and must be at least of as much advantage to the dealer as they are to the manufacturer.

Demonstrations. This topic has already been discussed under Demonstration Plans. A demonstration by a salesman may be made in the regular course of his selling or he may set aside a Saturday afternoon or time between trains when he steps behind the counter and gives a practical demonstration of the best way to sell his product. Many a salesman has been able to enlarge his order and win the friendship of the dealer by a little service of this kind which shows the dealer that the salesman is interested in the final sale of the goods fully as much as in his own sale to the dealer. The benefit from this kind of work is not unmixed for the salesman will profit by coming in contact with the consuming public and getting their reaction to his merchandise.

Temporary demonstrators are sometimes supplied by manufacturing houses, who travel from store to store, stopping for a short length of time to teach the clerks how best to sell and also to help introduce the product to the consuming public. A dealer secures the help of the demonstrator under some plans by the purchase of a certain amount of the product.

A permanent demonstrator is more often supplied to department stores or very large stores than to the smaller type. In this case the manufacturer is paying for an expert sales person who is working for the benefit of the dealer. A demonstration of this kind loses something of its value when it becomes "a part of the scenery."

Door-to-door Canvassing for the Dealer. This kind of work is carried on under the direction and at the expense of the local retailer. Mechanical devices such as are used in the kitchen, products that the consumer would not think to call for, and products best demonstrated in the home, such as the phonograph or radio, are subject to this kind of selling. It is sometimes handled by telephone appointment, particularly in the case of the radio.

This is a difficult type of selling unless the canvasser is well trained. Courtesy combined with persistence in order to obtain an opportunity for demonstrating are both necessary. The dealer runs the chance of offending his

customers and great care should be taken in selecting the canvasser for this kind of work.

Samples. The secretary of the Exclusive Distributors Association of Columbus, Ohio, has outlined some ideas on sampling campaigns from which we quote:

1. If a company is seeking national distribution, any town is better to begin with than the company's home town.

2. If the product is breakfast food or something similar the most logical time for sampling is the spring. Canned goods suitable for picnics, insecticides, face creams, etc., are other seasonal items.

3. If the company has limited capital, it is possible to sample one town and wait for returns. This money in turn can be invested in another distribution.

4. If the product is to be tested for national consumer possibilities, sampling will quickly show whether there is a probability of general sale.

5. If the company wishes to simplify its plan, it can test its different products in similar towns.

6. If the samples are medical, free distribution is prohibited in many states.

7. It is well to include every home in any one neighborhood selected, in the distribution.

8. If children are to be appealed to, distribution should be made at their homes, not on the school grounds.

9. If the advertising writer has anything more to say on the circular, let him say it. One company is distributing a four-page newspaper telling the whole sales message without cramping. The price for distribution remains the same for literature weighing up to fifty pounds a bag.

10. If dealers are not supplied with the merchandise, it is well to ask that the distribution take several days in the town. This gives the jobber a chance to supply dealers in one section and to reorder when the distributing produces a demand.

When a sample is given away by the dealer, with a word or two about the product, the customer is usually glad to receive it. The trouble with most free samples given the dealer by the manufacturer for this purpose, is that they never reach their proper destination. If the free sample is an original package more often it finds its way to the dealer's shelf and is considered as bringing that much net profit.

Free delivery of samples from door to door is limited by law and is not as popular as it was in years past. If the sample can be placed in the hands of the householder, this kind of distribution is good but expensive. The same applies to distribution on the street.

Samples offered through advertisement and sent in response to request are thus expected and are appreciated on receipt. Samples sent free through the mail from the manufacturer are usually sent on the basis of lists supplied by the dealer, unless there is a particularly accurate mailing list in the hands of the manufacturer.

Original packages to be used as samples are often sold by the dealer at a reduced price in order to get an introduction. When a new package is to be introduced the old package and the new are sometimes put together as a combination and sold by the dealer as an introductory package at a reduced

price. This allowance by the dealer usually comes back to the manufacturer as an expense which he charges to advertising. Sampling through advertisement or in any other way is usually charged to the advertising account and is rightly an expense to be carried in this appropriation.

A case of full-size packages is sometimes given for sampling with ten cases purchased or some similar arrangement. This is a rather difficult kind of sampling to obtain through the dealer. Usually the goods do not come along until some time after the salesman has explained the deal and, when opened and put into stock, the fact that a certain amount was to be distributed free is forgotten. This is not true in all cases but it is a chance that the manufacturer runs, without any reflection on the intent of the dealer.

Movie or Theater Tie-up. Advice is always given in advance as to what movie or play is coming to the local theater and many times a tie-up to the subject or the movie itself can be made by the dealer through his window or through merchandise offered in his store. An illustration of this is the tie-up of Rogers Peet and Company advertising with the legitimate theater which is so planned that their program advertising always has a hook up with the play then on the boards. This tie-up may be made by a reference to a certain type of clothing that is included in the movie, or a geographical location, or an artist who has endorsed the product in question. People like timely advertising and the dealer gets the name of being up to date when he can tie up in this way to current plays.

The Chesterfield Company made a good hook-up with the movies in their film "Memories" which was incidental in its advertising and connected the Chesterfield name with attractive pictures of bygone days. Commercial films get public distribution when the advertising is kept incidental to the value of the picture as an entertainment or educational feature. Where it is not possible to get public distribution through the theaters there are many ways of getting it through private and semiprivate exhibitions. Such a film must carry human interest so that it is interesting as a film. Preparation of these films must be by professionals, not by amateurs.

Combination Sale of Product and Allied Items. The association of ideas through the placing of related merchandise side by side will encourage the consumer to purchase more than originally planned. An example of combination selling is found in the Marshall Field windows at Easter when one whole window is given up to a complete toilet with the accessories near by so that hats, dresses, shoes, gloves, parasols, and all of the things that go to make a complete ensemble are displayed. Shoe stores have put in handbags matching the color of the leather in the shoes and have found that it makes a profitable addition to their sales. In the grocery store you find crackers and cheese side by side, or doughnuts and coffee; a head of lettuce, a bottle of salad dressing, and a can of shrimp make a complete salad. A Gillette safety razor and Palmolive shaving cream, neckties with handkerchiefs to match—many combinations can be worked out in every type of store. More and more are windows made to present combination sales and allied items rather than a number of odds and ends which leave no impression on the passerby. Zipper suits for children are matched up with an aviator's cap. A box of tools increases the purchase. Stationery is displayed beside a

fountain pen and stand. Such associated items help increase sales and make the "plus sale" so valuable in reducing the cost of selling.

Advertising Inquiries Sent to Dealers. Inquiries received through advertising and sent to dealers are no longer making much impression on the dealer. The inquiries should be used by the salesman directly with the dealer. He can go over the names with the dealer so as to show the value of the inquiry or else arrange to go out and make a call upon the inquirer and turn the inquiry into actual sales for the dealer with resulting profit.

Some manufacturers are satisfied if they answer an inquiry with printed matter trusting that this will lead to the purchase of the merchandise. Where the number of inquiries from an individual city or town is very large the salesmen can use them to advantage by personally presenting them to the dealer after complete information has been sent to the inquirer. The case can be presented to the dealer that if he does not supply the demand that has been created, some other dealer will.

Letters to Consumers over Dealer's Name. A letter that is written as a dealer would write it, prepared by the manufacturer and mailed by him to a list supplied by the dealer, is good advertising. Care, however, should be taken that it is in the language that a dealer would naturally use. Customers receive so many letters of this kind that they are rather skeptical.

Recommendation by a dealer of a certain product he wants to sell, will have its effect upon customers who have grown to have confidence in him and in his statements. The dealer must be careful what he allows a manufacturer to send out over his name. He values the prestige he has built up with his customers and does not want anything to happen that will break it down.

A much more effective use of this method is to send the letter to a carefully selected list limited to those who are known to be able to buy if the letter should prove convincing. An indiscriminate distribution of letters over the dealer's name does not bring returns commensurate with the expense.

Broadsides to Consumers over Dealer's Name. This kind of mail matter is the exception rather than the rule. Broadsides are more usually sent to dealers. Where such a broadside illustrates a machine in action and the message requires considerable space and color this method may be useful.

Missionary Sales for Dealer. Missionary selling is selling to the retailer at the expense of the wholesaler and the manufacturer. It is done because of a desire to introduce new goods more rapidly than would result from advertising or the normal sales activity. In some cases the jobber asks the manufacturer to create a demand before he takes the goods into his stock. The method is to send a special salesman around among the dealers to take orders which will be delivered through the dealer's wholesale house. The great weakness of the method is that many of the special salesmen's orders are not *bona fide* or are given by the dealer to get rid of the salesman and with no intention of making the purchase from the jobber.

The missionary or specialty salesmen must be of high-pressure type, able to call on a stranger and get an order on the first call. Regular salesmen on the territory are usually resentful of this kind of work unless they receive credit for the business obtained. The tendency on the part of the missionary

salesman is to overload the dealer, thereby spoiling business later for the regular salesman.

In some cases a specific charge for the sale is made. The Vortex Manufacturing Company of Chicago tried this out on the basis of charging 10 per cent for all orders the missionary or specialty men took, representing either new or repeat business up to a certain amount. Above that amount quantity orders were made at a lower price so the charge back was reduced to 6 per cent. On very big orders sales prices were still lower so no charge back was made. The blanket deduction from discount would particularly apply where there is a charge for house to house demonstration work which is paid by the department or agency carrying the article in stock. In many cases this is also charged where a demonstration is made in the retail store and the leads are followed up with house demonstration by the man in charge.

Prize Contest for Clerks. A contest for clerks, paid for in prizes of cash or merchandise, should never be used without the 100 per cent approval of the dealer. It insures special attention on the part of clerks to the merchandise in question and many dealers object to this because they claim the time spent on this special merchandise is lost from other lines and the total nets a loss. This depends, of course, on the style of merchandise, the kind of contest, the prizes offered and the interest of the clerks. Where there is no objection on the part of the proprietor a carefully outlined contest with good prizes will enlist the interest of the dealer's clerks and increase the volume of sales in a store.

Prize Contest for Consumers. Contests of this kind are usually conducted by inducing the consumer to save labels, cartons, or something pertaining to the merchandise. Sometimes it is a contest to choose the name of a product or a vote for something. Probably the contest for a name is the most popular with consumers.

Premiums to Clerks. It is claimed that there are many houses in the west that have been furnished from attic to cellar with premiums given by the Wrigley Company. This method of rewarding clerks should always be checked with the proprietor to be sure that he has no objection.

Premiums of practical value awarded on the point system, that is, so many points entitling the clerk to a choice of certain prizes, will bring the best results. Premiums sometimes take the form of what is known as "PM" which is an offer to the clerk of so much on sales of the merchandise within a certain period of time. Sometimes the dealer will put a "PM" on merchandise on which he is overstocked and wishes to move rapidly. Drug stores are well adapted to this kind of selling as also are department stores of certain types. The higher class proprietors are not willing to have a manufacturer give premiums to the clerks as they wish to keep the remuneration of clerks entirely within their own control.

Training Dealer's Clerks. Nothing is more important than that the dealer's clerks thoroughly understand the merchandise they offer for sale. Meetings held after hours for the dealer's clerks by intelligent salesmen from the manufacturer are welcomed by proprietor and clerks. Every clerk has the idea that eventually he would like to be a salesman on the road and given a chance to learn salesmanship from a successful salesman he takes in all he can get.

Successful training was carried on by a food shop in Philadelphia. Every morning when the clerks arrived they found a certain number of packages of food that had been opened, with a typewritten story beside each, and every clerk was obliged to taste, investigate, and read before he went behind the counter. Then each one was supposed to push the items that had been brought to his attention for the day.

The larger department stores maintain schools for the training of retail clerks in merchandising. Teachers with a knowledge of pedagogical method accomplish the best results. Store employees or even salesmen do not get the same results that a practical teacher well informed can get. Courses in retail salesmanship are available from many sources, and these can be adapted to the use of individual businesses. Promotion in many stores is dependent upon the clerk's success in such courses. It is more than a training in regard to different kinds of merchandise. It is a training as to how to meet the public and make successful sales. It is especially necessary that a training course be given on mechanical products, not only to the people who are selling but also to the people who are depended upon to give service. In many cases a button or diploma is evidence that a clerk has graduated and these are worn and shown with pride by the clerks. It is tangible evidence that they have reached a certain degree of achievement.

For Dealer Use. There are various items that can be furnished to the dealer which will be of assistance.

Dealer's Survey. The sales promotion department can sometimes supply information that will enable a dealer to understand better what the possibilities in his town or city may be. Or the dealer can be instructed how to make a survey, for example of the number of houses that are lighted by electricity, those that have telephones, those that have radios, etc. Any information of this kind will give him a better understanding of what growth is possible for his business and the kinds of merchandise he can sell.

Newspaper Cut and Copy Service. The advertising department or the sales promotion department can supply to dealers a newspaper cut and copy service. This consists of made up advertisements in the form of cuts that newspapers can use, copies of trade-marks and packages, reproductions of advertising that has been running in other papers, and even the preparation of special copy set up in cut form for immediate use.

Work of this kind by the dealer can best be carried on through a well defined advertising campaign. Sometimes the manufacturer is willing to enter into a fifty-fifty arrangement whereby 50 per cent of the bill for advertising over the dealer's name is paid by the manufacturer. In this case the manufacturer is especially interested in the kind of copy that appears. Many advertising managers are willing to guide a dealer in his local advertising even though no fifty-fifty arrangement exists. The local dealer gets the advantage that his copy appears concurrently with advertising of the product in other newspapers and magazines.

Catalogue for Dealers' Distribution. Much merchandise does not have a catalogue. Where there is a complete line, however, catalogues are necessary to the dealer and are very often reproduced in cheaper form for general distribution. Some catalogues are beautifully bound so that they will be

prominent in the dealer's store; some are in loose leaf form so that additions and subtractions can be made at various times. Catalogues are particularly necessary for dealers where it is impossible for them to carry a complete line and they depend upon ordering through the jobber or manufacturer as items are needed. Complete information in this case should be included in the catalogue so that there will be no misunderstanding in placing an order.

Envelope Insertions for Dealers' Distribution. These can often be the same inclosures that are used to advantage in the original package. There are, however, two opinions in regard to the use of this kind of advertising. Evidence secured by the Phoenix Mutual Life Insurance Company indicated that inclosures cut down the per cent of returns on direct by mail letters. An envelope can be so stuffed with various inclosures that the whole lot is thrown into the waste basket without being read.

Booklets for Dealers' Distribution. What has been said about envelope insertions applies to a certain extent to booklets, although booklets can be made of much greater value and will be taken more seriously. There must be a real reason for the booklets and if they are distributed by the dealers, they should go only to those who will be interested. The dealer should stamp his name on the booklet for the tie-up with his own store. The use of booklets has already been discussed under Booklet Plans.

Special Price Coupon for Retailers' Distribution. Coupons are used by dealers to stimulate the retail trade. There was a time when manufacturers paid something toward this kind of distribution but it has very largely developed into a retail device. There is a special form of coupon called the voting coupon which eventually results in a special price. This is not a phase of sales promotion work, however, that is taken very seriously by many manufacturers.

Publicity. Publicity is used to the best advantage when supplementing advertising.

Movie Slides and Films. There was a time when the advertising movie slide could be placed at a price at almost any movie house. Even now some of the smaller theaters will carry a campaign of this kind, although it is becoming more difficult to place such films. There is an improved development of the film, called the commercial film, that is receiving fairly wide publicity. This has a real scenario, the advertising is small in amount and the plot magnified, so that it often gets prominent display. In many cases the advertising is so incidental that people do not realize they are looking at advertising.

Metal Signs. When metal signs could be attached to trees, fences along the side of the road, and other prominent places, there were many of them used. They have their place in sales promotion work at the present time, but discrimination has to be used in their posting. This kind of sign on the highway giving mileage is sometimes worth using for merchandise which is classified as incidental purchase. Metal that does not rust can be used for a designating agency sign and also becomes more or less of a permanent fixture inside the store.

Canvas Banners. The use of these is very largely on confectionery stores, dry good stores, or stores where there is fadeable material in the window,

and they can be used as sun curtains during the sunny part of the day. The canvas itself carries advertising matter, often an agency name for a product in the store.

Decalcomanias, both imported and domestic, are made in beautiful colorings and add to the attractiveness of windows on which they are placed. By their use a sales organization can leave a trail of designating signs over their entire territory which will last for many months. Care should be taken that the colors are such that they will blend with whatever merchandise is placed in the windows. They should be small in size so as not to obstruct the view and should tell their story in a few words. The preferred positions for "decals" is eye height on the window or store door.

Store Cards. Many of these cards are originally made for street car display. An extra quantity is purchased, a cheap frame made, and they become an addition to the store. There is a firm in Vermont that specializes in the manufacture of these frames for store cards. Other cards are made to hang from a chandelier or bracket, and others can be tacked on cases or in any position for temporary use. Some of these are made very cheaply, others are of real beauty and remain in use for a considerable period.

Business Shows. There is a divided opinion in regard to business shows. The outstanding ones are the Aeroplane Show, Automobile Show, Motor Boat Show, Radio Show, and Office Appliance Show. Apparently these bring good results because the manufacturers go into them year after year, and great care is taken to make an interesting exhibit. They do furnish a means whereby progress in the industry can be followed as in no other way. The smaller type of business show, such as the food show, has passed from its original attractiveness and unless put on by people who understand their business, it produces very little for the manufacturer. There still remain county fairs and state fairs where display is made and at certain points attracts the crowd. It is a question as to the value of such business shows unless selling privileges are allowed and if they are allowed, it must be under restrictions that prevent the show from being turned into a Coney Island.

Calendars. Many advertising managers and sales promotion managers turn up their noses at calendars, but it is well to remember that the calendar is a billboard of small size placed in a customer's house to stay there for twelve months. Some manufacturers make the advertising so prominent that the calendar loses its attractiveness, others maintain due proportion and find their calendars in great demand. There are advertising calendars which are sold by the manufacturers at a price because of the beauty of the design, subject matter or material.

Fans. These have a short season, but advertising fans distributed when needed make friends for the dealer supplying them. We have seen them in churches, at concerts, and at picnics, carried around all day long—good publicity for the thoughtful dealer.

Blotters. This is a selective medium and can be used by manufacturers who have a product that will appeal to office people. Banks, insurance companies, restaurants, and the like use this type of advertising.

Novelties. These are of many varieties, such as the booklets used by insurance firms to get appointments, the small brushes given by the Fuller Brush

salesmen to get a hearing, banquet novelties, or fountain pens for men who write orders. The "feature match book" advertising Squibbs Shaving Cream and Dental Cream is novelty advertising. The paper match is printed in the form of the tubes of the product, the cap being represented by the head of the match.

Trade Papers. The proper preparation of trade paper publicity should be a serious part of the sales promotion manager's job. His close contact with dealers all over the country puts him in touch with valuable information which they are glad to print if it has actual news value. Those who are interested in getting advertising in the trade paper should get it in the usual way and pay for it. There are, however, kinds of information, especially such as can be illustrated by pictures, which dealers all over the country are interested in and the trade papers are glad to print. Ideas as to successful campaigns, unusual windows, unusual store arrangements and many other things properly presented, will find their place in the trade paper.

So we come to the close of a chapter that could well be extended into a book. To exhaust the subject would mean exhausting all there is in advertising and sales, for sales promotion touches each and every part.

CHAPTER IX

DETERMINATION AND CONTROL OF MARKETING COSTS

By H. G. CROCKETT, *Engineering Partner, and ASSOCIATES, Scovell Wellington and Company*

All of the marketing functions discussed in the foregoing chapters may be well planned and executed, but since net profit is the goal of every business enterprise, it is essential that the total cost of all of these functions be something less than the total gross profit. It is therefore necessary to know just how much each of these functions does cost, also how much they should cost, not only in total but in some detail and in terms of measurable units.

It is also necessary to establish some cost control mechanism if these costs are to be currently measured and kept under control.

This chapter therefore deals with the whole problem of marketing costs, first offering some general comments on the factors that have caused the steady increase in selling costs in recent years.

There is next a rather detailed explanation of how selling costs are determined, and of the control mechanism that should be set up. Finally, there are illustrations of the kind of facts that are brought to light through an analysis and study of selling costs, and which have led to reduced selling costs and increased profits.

General Comments. It will undoubtedly help to a clearer understanding of this subject if we review the history of the causes which have brought selling costs to the point where they are now of major importance, if not uppermost, in the minds of all executives who have to do with the distribution of any commodity.

Until a few years ago little attention was paid to marketing costs, the emphasis being entirely on manufacturing costs and problems of production. The country was large and growing rapidly and the needs of the people and their capacity to absorb all manner of products seemed almost unlimited. The gross margin was ample and therefore there was little necessity for any very thorough analysis or study of selling costs.

That situation has now changed. It is still a fact that the majority of manufacturing companies do not know as much as they should about their manufacturing costs, but, as compared with twenty-five years ago, the situation has greatly improved. Both colleges and professional associations have done much to spread the gospel of good cost accounting throughout the United States, and the principles of manufacturing cost accounting are generally well known and recognized.

The situation which existed in relation to manufacturing costs some twenty-five or thirty years ago was true of general and selling costs until very recently. The total cost of administrative and selling activities was of course known, but little attempt had been made to allocate these costs to different territories or products. If there was in some instances an attempt to distribute these expenses to a few general and quite different lines of product, that was about as far as it went. The last few years, however, have brought about a very noticeable change.

It is not necessary to describe here in detail the changes in the economic structure of this country since the World War—the general prosperity, the wide diffusion of capital, and resulting increase in demand for every variety of product, luxury as well as necessity.

The war left us with greatly increased manufacturing facilities. The necessity of employing that unused capacity brought about the invention of new products, and the inauguration of extensive sales and advertising campaigns to create a demand for the products. As these were successful, more manufacturing facilities were created. Then, too, as improved production and manufacturing methods had become known to all manufacturers the emphasis of competition naturally came to be placed on selling and distribution rather than on manufacturing.

The result has been that as manufacturing costs have decreased or remained stationary, general and selling costs in total and per unit have gone up. In other words, the increased cost of selling has in many instances more than offset the gross profit from the extra volume, particularly since in many instances that gross profit has been decreased by a reduction in selling price—one of the most common methods employed to increase the volume of sales.

It is natural, therefore, that many companies should recognize the need of more accurate and detailed information regarding general and selling costs, in order that this expense may be kept under control and reduced if possible.

While a few companies have made great progress along this line, and have conducted many investigations in various branches of administrative and selling activities, it is fair to say that work in this field of cost accounting is still very much in the experimental stage. Those companies that have made the most extensive studies and investigations are the more certain that they yet have much to learn, and it is still true that the overwhelming majority of companies have done practically nothing in this field.

Relation of Manufacturing to Selling. Coordinating the activities of the manufacturing and sales departments is perhaps the most important, and yet one of the most difficult problems to solve. The manufacturing department would like to be able to produce only standard goods in large quantities, and the sales department would frequently like to accommodate their customers by giving them whatever they want, even if that is slightly different from standard.

Before competition was quite so keen, and the gross margin so narrow, a reasonably satisfactory solution could be obtained from an accurate knowledge of manufacturing costs and the effect of volume production on them. Under present conditions that is not sufficient, and it is necessary to know all that is possible about selling costs: what products and what territories yield the

greatest profit, what effect volume of sales has on selling costs, what are reasonable standards of selling costs, and what volume must be obtained in each territory and in each line.

The Problem. Accurate knowledge of selling costs is important for two reasons: to determine an accurate total cost as a basis for a selling price, and to make it possible to control and reduce these costs. The latter is by far the more important reason.

If setting the selling price were the sole purpose, it would be sufficient to know only the selling cost of the line as a whole, since the base price must be the same to every customer and in every district. In many lines, it must also be the same for a wide range of sizes, colors, shapes, etc.

Different Types of Organizations. There are, however, so many different types of sales organizations, so many methods of distribution which may be employed, and withal such a variety of products which may be sold by the one company, that it would seem worth while to know all that is reasonably possible about the cost of these various methods and activities, if one is to decide which method is the most effective and therefore the cheapest.

For example, there is the common plan of direct representatives selling to other manufacturers, wholesalers, and retailers. Goods may be distributed entirely through jobbers, with the company's direct representatives doing only promotional or missionary work. There are many organizations selling direct to the consumer on the house-to-house canvas plan. Sometimes the entire output is sold through a selling agent.

Then there may be branch sales offices, and branch warehouses, or goods may be handled by agents on consignment. These are only the more common types of sales organizations, and there are many variations of these. Many companies employ several of these different methods, along with direct mail selling, and frequently are in doubt as to which is the best selling method to use.

It cannot be claimed that knowledge of selling costs per se gives the answer but certainly it will show where the weaknesses lie and where corrective methods are most needed.

The principles here set forth will apply to every type of what may be called field selling or distribution, whether by a manufacturer or wholesaler. Retail (store) selling involves many quite different problems and no attempt is made to cover that phase of distribution in this chapter.

Considering the product itself it is of course important to know the net profit resulting from each line; how much the volume of any unprofitable line must be increased to produce a profit and, naturally, the expense that will be necessary to get that increased volume.

As regards territories and salesmen, it is necessary to know the net profits produced from each territory and the causes for any fluctuation from the standard; it is important to know the net results of each salesman's efforts—how much of his work is promotional or servicing as distinct from actual selling; whether the territory is sufficiently cultivated; whether the territorial division should be changed; and whether it is more profitable to have agents working solely on commission and handling other lines, or to have direct company salesmen.

Should branch offices or branch warehouses be established, and should they be sales and service offices only, or should some of the accounting and other work be handled by these branches? Which class of customers is the more profitable—the wholesaler, the retailer, or the consumer?

These are only a few of the more important questions that must be answered if the business is to continue to be successful. Many more facts, perhaps of less importance, will become evident as general and selling expenses are analyzed and studied in connection with the varied activities coming under this heading.

In approaching the problem of any one company the first step is the analysis and distribution of the actual general and selling expenses covering a recent period—the period to be of sufficient duration to present at least a complete season—usually at least a year. The next step is the determination of standards for each item of expense and the setting up of the necessary routine for the measurement and control of the actual expenses.

Treatment of General or Administrative Expense. It is of prime importance that there be a clear understanding of what should be included in general and selling costs. It might seem sufficient to define general and selling costs as including everything that is not manufacturing, but unfortunately there is some difference of opinion as to what constitutes manufacturing costs.

This is not because there is any serious misunderstanding as to where the manufacturing function stops and the selling function begins. This will usually be when goods are delivered to finished stores, but in some instances, particularly when goods are manufactured on customers' orders and no storage is necessary, it will be when goods are delivered to the shipping room floor.

The difference of opinion is in regard to what is to be done with the so-called administrative functions or expense. The purely administrative expenses would include the salary of the chairman of the board of directors, president, treasurer, and possibly the secretary of the corporation, the expenses of their offices, and any other purely corporate and financial expenses; but many companies have added to this group all expenses connected with accounting and general office routine. This leaves in selling expense only those items that are directly identified with sales and advertising and shipping departments.

In theory, all expenses may be considered as either manufacturing or selling, and it is evident that these so-called administrative items represent activities that are really for the benefit of producing goods or distributing them. There are two methods of handling this group of administrative expenses, each of which has its advantages and disadvantages, and the accountant will have to decide which method best suits the particular organization under consideration.

One is to analyze each administrative department, or each item of administrative expense, and decide how much belongs to manufacturing and how much to selling. Much of this distribution may be purely arbitrary, but some items can be distributed accurately.

For example, the president of the company may have to make an arbitrary distribution of his time, and all of his office expenses will go along with his salary. On the other hand, practically all of the accounting department

Fig. 1.—Chart of accounting plan for the distribution and control of selling expense.

activities can be divided between work for the manufacturing department, such as handling accounts payable, and work for the sales department, such as handling accounts receivable. If it is worth while, all general office services can be analyzed and a fair distribution made. If this method is followed all expenses are then either manufacturing and included in manufacturing costs; or are selling expenses, and included in selling costs.

The other method is to leave in an administrative group those items which cover purely administrative functions or which do not readily lend themselves to distribution between the two major activities. This total would be expressed as a percentage of manufacturing cost plus selling cost, and added to the sum of those two to give a total overall cost.

The explanation following, and the accompanying chart, is intended to cover the principles of either plan. It deals with every class of expense that may definitely be considered a part of selling, and also an item of general selling expense which represents the share of the administrative group belonging to selling. This group may include only purely administrative expenses already mentioned and also accounting and general office items as well.

The chart accompanying this explanation should help to an understanding of the classification and distribution of expenses through the various functions and auxiliary departments to the direct sales units and products.

Distribution of Elements of Selling Expense. While it is important to know the cost of selling one line of product as distinct from that of another, the first or primary distribution would naturally be to the various direct or auxiliary sales departments, and to territories.

The reason for that would seem to be obvious. Since control and measurement of expenses is the prime object, and since reduction of cost can be effected only through such control, it is necessary to allocate all expenses to what may be called the operating units, just as in determining manufacturing burden costs, all expenses are distributed to departments or operating centers.

The sales territories may be considered as the direct or producing units, and in many instances a territory is the district or customers covered by an individual salesman. All other departments of selling are service or auxiliary centers. The chart presents a list of the expense elements and of the departments or functions of a sales organization. Probably every sales organization performs every one of the functions mentioned, but only the larger organizations would have a separate department for each of them.

In the foregoing paragraphs of this article we have explained the distinction between manufacturing and selling costs, and administrative and selling costs, and indicated the present-day necessity for analyzing and allocating definitely the expenses arising out of the selling and distributing functions of a business so that they may be efficaciously controlled.

We shall now explain the mechanics of distributing the selling expenses so that definite knowledge concerning the purpose for which they were incurred and where they were incurred may be ascertained and responsibility definitely fixed. In order to make this explanation completely lucid, the chart accompanying this article will serve to amplify the description and give a mental picture of the routine involved.

So that the method of distribution and its successive steps will be entirely clear from the beginning we shall first briefly describe the plan that is followed. Primary elements of selling expense are allocated either to selling and distributing departments or directly to specific products and sales territories, depending of course on the character of the expense. The nature of some expenses is such that they can be charged directly to territories and to specific products in those territories. Other expenses must of necessity be charged to departments. After all the expenses of a department are collected and totaled the total amount is then distributed to the various sales territories on whatever basis is the most logical, and the one generally recognized as being most nearly correct. The final step, after all expenses have been charged to territories, is to allocate them to the various products and classes of products that are sold in each territory. When this distribution is finally completed, it is readily known not only how much it costs to sell in each territory, but how much it costs to sell each of the company's products. As we point out later in this chapter, this information is of inestimable value, since it permits comparisons of expense to be made between different territories for the same product, and when used with the sales figures for that product it provides an excellent measuring device for marketing effort.

Distribution of Elements of Selling Expense. A. *To Departments or Functions.* 1. *Fixed Charges.* The fixed charges on the land and buildings are prorated to the various functions or departments shown on the chart on the basis of the number of square feet of floor area occupied. The fixed charges on equipment, such as desks and other office furniture are charged to the functions on the basis of the value of the equipment used.

2. *Home Office Salaries.* Salaries of individuals employed in the Home Office are distributed to the functions which they serve. In some cases an employee's duties take in more than one function and in these instances salaries must be divided according to the service rendered to each function and charged accordingly. A portion of officers' salaries will probably be considered as being applicable to sales and since they would be of a general sales nature they would be carried to the function entitled general selling expense.

3. *Advertising Agency.* All of the expense in connection with advertising that is placed by an advertising agency will be distributed to the advertising function. Subsidiary records in the advertising department should reveal how much of this expense is incurred for the different kinds of advertising.

4. *Entertainment.* Expenses incurred by members of the home office for entertaining will generally be charged to general selling expense, but if they are in the interests of any of the other functions those functions will be charged. For example, the entertainment expense of the sales manager will be carried to the sales manager's office, and the entertainment expense of the credit manager will be distributed to credits and collections.

5. *Traveling.* Traveling expenses of the sales manager may possibly be charged in some instances to territories and products, but more often they will be distributed to the sales manager's office. Other traveling expenses that are incurred by employees of the Home Office will be charged to the functions which they serve.

6. *Supplies.* A study of the accounting records will show the amount of supplies used for each of the functions listed. Of course some of the supplies may be directly chargeable to certain sales territories and products and, for these supplies, the distribution would be to the territory and product affected.

7. *Telephone and Telegraph.* Telephone expense is charged to the functions, usually by an estimate of the number of calls handled for each function. However, a much better method is to have the telephone operator keep a record for a period of two or three months of the number of calls made by each department or for each function, and this record will provide fairly accurate information for allocating this expense. The out-of-town calls can easily be charged to the departments making the calls. Telegraph expense would be handled in a similar manner.

8. *Postage.* The amount of postage used by each department may be estimated but a record can be kept for two or three months, and this record will serve to estimate the distribution of the postage expense to departments or functions.

B. To Territories and Products. 1. *Salesmen's Salaries and Expenses.* The salaries and expenses of salesmen will be distributed directly to the territories in which they work.

2. *Commissions.* Commissions paid to salesmen or sales representatives can be definitely charged to the territories where they are paid.

3. *Freight Out.* An analysis of freight bills for shipping the company's products to the customer will indicate how much of this expense should be allocated to each territory.

4. *Parcel Post.* By analyzing the parcel post record it can be quite easily determined how much of this expense should be charged to each of the sales territories.

5. *Trucking.* If the trucks are owned by the company a burden rate per hour may be easily computed and the trucking expense can then be charged directly to sales territories.

If the trucks are owned by a trucking company the trucking bills should be analyzed in order to find out the amount of expense incurred for each territory and the charge to territories will then be made on this basis.

Distribution to Territories or Sales Units. Having distributed each element of expense to departments or direct to territories, the next step is to show how the total expenses of these several auxiliary services or departments are to be distributed to the territories or direct sales units. Each department or function listed on the chart will be taken up in that order.

The basis of distribution suggested is the one that would seem to cover most situations, and has been followed in many instances. If an analysis of the situation indicates that some other basis is more equitable, or accomplishes practically the same result with less work, obviously that is the basis to use.

Sales Manager's Office. This will include all salaries and expenses attached to the sales manager's office, except as he has assistants who devote their time to particular phases of the work. All expenses of this office should be distributed with the sales manager's salary. The sales manager will have to estimate (possibly make a little study) the distribution of his time, having in mind that he gives attention not only to the direct selling activities, but also to some or all of the other functions or departments.

Advertising. It is sometimes difficult to separate advertising from sales promotion and that is not particularly necessary. They are treated separately here only because the work may be handled by quite separate divisions. When this is the case advertising covers the writing or approval of copy, preparation and distribution of catalogues, booklets, and circulars, as well as the distribution of samples.

The total advertising expense is usually a comparatively large item, in many instances the largest single item of selling cost, and it is therefore necessary to give considerable attention to the distribution of this expense.

The cost of getting out catalogues, booklets, price lists, samples, etc., is made up of two kinds of expense; namely, the direct cost of materials and time of personnel devoted to those activities, plus the proper proportion of the overhead expenses of the department. This proportion is the result of the distribution of this expense on the basis of time or pay roll. The sum of these two component parts is then distributed to the territories and products for which the expense is incurred.

Catalogues are usually sent to all customers and prospects and the total expense of this item should be distributed to territories on that basis. At the same time a further distribution should be made between lines of product, and that division should be on the basis of the catalogue space devoted to each of the several lines. There may be a few occasions where it is necessary to recognize the fact that certain territories are not a market for some of the lines and therefore should not be charged with the full share of the total catalogue cost. In such cases the distribution should be first to the product lines and each line then considered separately.

The cost of price lists, booklets, and circulars will be treated in the same way. The distribution of the cost of samples offers no particular problem. With all of these items it is usually easy to keep the cost separate as between the several lines of product.

The cost of space in publications presents a somewhat different problem, although not a difficult one. It is easy to get the circulation of each advertising medium in each territory represented (assuming that the medium is not strictly local) and the distribution of the cost should be on the basis of circulation, weighted in some instances by the relative purchasing power, and also by territories which are not markets for certain products.

Sales Promotion. This may cover a variety of activities, from the study of sales statistics, and research and surveys in the field, to the introduction of new products and the opening of new territories. Sometimes the expenses can be charged direct to the territories and to the products benefited. Where the work is in the nature of a general promotional campaign, the division between territories should be on the basis of the potential sales or sales quota for the respective territories, on the theory that the effort is more likely to be in proportion to the expected volume than on actual sales.

Salesmen Training. There are so many different methods of salesmen training that it is impossible to establish any one rule for the distribution of this expense. Sometimes men spend a certain length of time in the factory, learning about the product and how it is made, at the same time attending classes and lectures. If they actually do work in the several departments,

their salaries (or at least an amount representative of the value of the work they do) should go into the cost of those departments. Otherwise their salaries, together with the salaries of the instructors and the necessary expenses, make up the total cost of salesmen training. This may be charged to the territories to which the graduates have been assigned.

Sometimes men are put in the field with more experienced men. If they later serve as assistants or junior salesmen in that same territory, their cost should be charged there. Otherwise, the total expense of training, including their salaries, is taken in total and distributed as suggested in the previous paragraph.

Estimating. By estimating is meant, primarily, the cost of estimating on customers' specifications, which is a very important activity with some companies. It may also include estimating on new standard product lines, or changes in existing lines. The expense of the former would be charged to territories on the basis of the number of estimates figured, perhaps weighted by the character of the product estimated and the latter on the basis of the actual or expected sales.

Mail-order Selling. In some organizations all of the selling will be by mail with no direct representation or solicitation, while in others a mail-order department is used to supplement salesmen's efforts, or to cover outlying districts where there is no direct representation. In either case the following explanation will apply. All of the expenses of the mail-order department will be collected and then distributed to territories on the basis of the number of mail orders received from each territory. There is not the same need for a territorial division, but it is advisable to divide the total mail-order territory by states, or into the units that would be covered by a salesman.

Service. Service departments are very important ones in many industries, such as the automobile, household appliances, office appliances, certain types of machinery, etc., and the activities may be quite varied. They may cover not only servicing and maintenance of the equipment, but also the matter of adjustments and allowances. Much of the expense can be charged direct to territories, and the balance will usually be distributed on the basis of sales of the product in dollars or number of units. It may be necessary to consider the total amount of equipment or product that has been sold in the territory or only the quantity outstanding that is still covered by a guarantee.

General Selling Expense. The treatment of this item is somewhat special in nature and has already been discussed at some length previously in this text.

Correspondents. Many organizations have a group of assistants at the home office, who handle the routine correspondence with customers and salesmen. Sometimes each correspondent covers certain territories, sometimes certain lines of product. If each one covers more than one territory it will be necessary to determine whether his time is divided equally over all territories which he covers, or to estimate just what the division should be. Possibly an analysis of the time spent over a short period will help in arriving at a fair basis of distribution.

Order Department. This department will include the interpretation and actual transcribing of the orders, and may sometimes include pricing, as well

as the keeping of necessary order records. The distribution will be on the basis of orders received.

Billing. This work is frequently combined with the order department, and the distribution should be on the basis of bills sent out.

Accounts Receivable. This department covers all work in connection with customers' accounts and the distribution would usually be on the basis of the number of active accounts, but may be on the basis of the number of invoices. It may also include sales analysis, various kinds of sales statistics, sales cost accounting, and budgets, and the cost of that part of the work would usually be divided equally among all territories.

Credit and Collections. The work of this division may be divided into two classes: that of passing on all orders for credit and approving the credit of new customers, and the collection of past due accounts. The amount involved is rarely large enough to warrant any separation, and the distribution would usually be on the basis of the number of orders.

Traffic. The function of the traffic department, as distinct from shipping or delivery, is to determine routings, check and approve rates, see that cars are available, handle damage claims, etc. The basis of distribution will depend upon the division of time to these several activities. Usually it will be satisfactory to consider traffic with shipping and assess traffic costs along with shipping.

Finished Stock. It has been previously pointed out that this department may be considered a part of manufacturing cost, but whether that or as a part of selling cost, the method of applying and distributing the expense will be the same. The stock room has to do with the physical product, and therefore the expenses may be expressed as a rate per unit of value or quantity of product and distributed to territories on that basis if not as a part of manufacturing cost of sales.

The expenses include power, light and the usual items of expense for operating a department of this kind, plus the carrying charges on the inventory. An analysis of the volume of the different lines of product handled and carried in inventory, the space occupied, and labor of handling, and the value, will indicate whether there should be more than one rate. Once the rates have been determined, it is a simple matter either to add this item as a part of manufacturing cost, or assess it to the territories as goods are shipped.

Packing and Shipping. This does not cover the standard container in which standard products are always packed, but only the outside shipping case or crate. The standard container (definitely identified with the product) is properly considered a part of the manufacturing cost.

An analysis and study of shipping labor and packing materials will show that standards or rates can be established for the several lines of products handled, the rates being expressed as a cost per dollar or quantity of product. With the rates established the matter of distribution is simple.

Freight, express, parcel post, and trucking charges (if not charged to the customer) should be charged direct to the several territories.

Delivery. Where companies have their own delivery service, each truck usually has its own route and there is therefore no difficulty in assessing this cost to the territories served. The cost may also be assessed to the several lines of products on the basis of pieces, bulk, weight or value carried.

Distribution to Products. Having now distributed all expenses to territories or salesmen or what might be called the direct sales units, the next problem is to apply them to the several lines of product handled. Many of the items of expense are readily identified to products, as has been pointed out in the paragraphs covering the distribution to territories.

The items which will usually come under this heading are advertising, stock room, packing and shipping, delivery, estimating, and sometimes sales promotion and correspondents.

There remain, however, some very important items, not so easily identified to products. These are salesmen's salaries and expenses, supervision, and, in fact, all expenses not already allocated to products. It is, of course, possible to analyze many of these items covering a given period and determine the relation to products, and that may be worth while. Usually, however, it will be satisfactory to group all of these items together, consider them as auxiliary to the salesmen's efforts, and distribute them with the salesman's salary.

It may seem difficult or impossible to determine any basis of distributing salesmen's time, particularly if each man handles more than one line, but the ratio of effort to results must be known, if only in a very general way, if sales and profits are to be increased. Many companies have found it very profitable to get quite detailed reports of a salesman's time, showing the hours spent in travel, waiting, selling, and in other phases of the work. Some companies keep this up only long enough to get an idea of the amount of time spent in these several activities (which is of course constantly changing) but most companies find the information of sufficient value to continue it permanently.

Such data will furnish a basis for distribution of the salesmen's time. It may be decided, for example, that irrespective of results, 75 per cent of a salesman's time is spent in selling one line, and 25 per cent on another, and that percentage will be used until a further study indicates that the ratio should be changed. It may be that number of orders, number of units, or cost or sales value, will be the most satisfactory basis. The only thing that is certain is that no one basis will fit all cases, but a thorough analysis of sales and expenses over a representative period will certainly indicate which basis will more nearly meet all conditions.

After all, as was stated earlier in this chapter, it is the distribution to the functions and territories that is of primary importance for the purpose of control. When the best basis available for distribution to products is used, the results may show the cost to be as low as 10 per cent in one territory and as high as 25 per cent in another. If the average of all territories and therefore for the complete line is 18 per cent and the gross margin is only 20 per cent, it is obvious that something needs to be done, and a difference in the method of apportioning only a part of the expenses would probably make no material difference in the results.

Repair and Parts Sales. In many industries the sale of repair parts and sometimes of repair work accounts for a very considerable volume. It may be that no further selling effort is necessary to get this business once the original equipment has been sold, but practically all expenses except salesmen's

salaries and expenses, advertising and sales promotion, or possibly a portion of those, do apply to this class of business.

That being the case, this is one instance where it may be of no value to distribute this expense pertaining to repair and parts sales to territories, since the control of the expense is not with the salesman but with the home office or branch office.

Cost Control Mechanism

General Comment. It has been pointed out previously in this chapter how the various selling expenses are distributed from their sources to the territories, and from the territories to the various products or lines of products. The usual results of this distribution of selling costs is the revelation, if it may be termed such, that the cost of getting the merchandise from the manufacturer, jobber, etc., to the consumer, has been too great or, at least, that it has been more in some territories than the circumstances would seem to warrant. It is therefore necessary to reduce and control these expenses.

It is not a new principle that costs are best controlled by comparing them with some standard measure or value. In other words, it is necessary to know how much a thing should cost before any decision can be made that the cost is too much. The first step in a cost control program, therefore, is to predetermine and establish unit standards of selling expense to which actual disbursements and costs may be compared in order to find out if they are excessive and by how much, and why. It should be borne in mind that cost control must be aimed directly at the person or function responsible for the expense, and the intent is to know exactly how much money each person or function responsible should spend or should have spent under the conditions which existed.

These standards, of course, cannot be picked out of thin air, but can be determined in a usable form only by careful analysis of the sources of expense. Furthermore, no standard should be merely the average of past expenses, but should be developed by analysis of the efficiency with which the work is performed in the light of how much expenses should be under present or forecasted conditions. While it cannot be said that any set of conditions will be constant, still some set of conditions must be assumed before any kind of a standard can be established. The setting up of the conditions may be treated in either of two ways. If the circumstances of the business are such that future conditions may be predetermined with some reasonable degree of accuracy, then the problem is comparatively simple and involves a single reliable quota. If, on the other hand, there is no experience in sales forecasting, and it is felt that it would not be possible to predetermine conditions with a reasonable degree of accuracy at the start, then the flexible feature of expense control may be adopted, until such time as the sales forecasting program has attained some degree of perfection. At least the entire range of possibility of conditions from one extreme to the other is known, this range may be broken up into steps and each step considered as an independent forecast. For example, assume a volume of sales varying between \$500,000 per annum and \$1,500,000 per annum, and that there is no certainty where

sales will be between these two extremes. Therefore, this range from \$500,000 to \$1,500,000 would be subdivided into steps, each step representing a change in magnitude sufficient to cause considerable change in effect. These steps should be close enough to reflect all important changes in resultant expense and, on the other hand, as far apart as possible to minimize the amount of work involved. For the purposes of outlining a program of selling costs control, this flexible feature will be assumed and the setting of standard unit selling costs shown for a number of steps in the range of possible sales volume.

Definition of the standard is in order at this point. What is sought is a logical, sound, and reasonable unit of value for purposes of judging results. The conditions under which the standards will be set up must be within the range of probability, must reflect neither extreme, must be reasonably attainable, and in every way normal. Likewise, the standards themselves must be within the range of probability, logically attainable, and in every way normal. It seems, therefore, that the word normal is more applicable and it will be used henceforth in this text.

Some of these normals will be fixed for all volumes of sales, others will vary directly or inversely in proportion or by steps. As stated previously, normals should be developed by analysis but in some cases normals for territories or products will be distributed portions of normals for functions or departments.

Normals of Elements of Selling Expense. Next consider the method of establishing normal values for elements of selling expense within each of the departments or functions involved. Among these elements of expense will be some items which are common to many departments or functions and will therefore have to be distributed accordingly, and there are others which belong wholly to and are therefore chargeable only to certain specific departments or functions.

A. Distributed to Functions. 1. Rent. Under the first group which is to be distributed we have the item of rent, or corresponding fixed charges for office space, light, heat, maintenance, etc. Briefly, this item is more or less fixed, except as permanent reductions or enlargements are made in the various departments. If the range of possible sales volume reaches a point which would require permanent increase in space facilities, it will be necessary to estimate the space charges beyond the point of present space arrangements. Otherwise the normal values for this element of expense will consist merely of the fixed charges incurred under present conditions.

2. Salaries and Expenses. Under this heading are three types of salaries and expenses, namely, executives', office employees' and salesmen's.

Officers' salaries and expenses are more or less fixed, regardless of the volume of business, except possibly in the case of a very large organization having its sales function rather finely divided, in which case a change in the volume of sales within the range of possibility might require the establishment of new departments or the consolidation of two or more existing departments. in which case there would be a radical change in the amount of money involved. Barring this, however, the executives' salaries would be the same for the lowest extreme in the range of volume of sales as at the upper extreme. With this, of course, should be included any bonuses paid to sales executives as a result of sales volume.

Executive sales expenses are more likely to vary in proportion to sales volume, although here we may have a case where the sales executives go out into the field and perform more intensive promotion or missionary work during periods of low sales volume than in periods of high sales volume, which would tend to keep the sales executives' expenses constant. The item of officers' salaries is considered to be among those included with other general administrative expenses and is therefore distributed as shown on the accompanying chart. (See p. 252.)

B. Charged Directly to Functions. 1. Salaries and Expenses. Office clerical salaries should vary more nearly in proportion to sales volume, for the reason that the functions become more finely divided and it becomes possible to relate the number of persons employed to actual volume of sales. For example, if the number of bills should increase or decrease by an amount equal to or greater than the capacity of one clerk, then it becomes necessary to add or subtract one such clerk. In each department or function, therefore, there should be a change in the normal for office salaries whenever the volume of work changes enough to warrant a change in the number of clerks employed.

The degree to which the salesmen's income varies in proportion with volume of sales depends upon the plan of wage payment for salesmen. Salaries, of course, remain constant as long as the salesman remains on the pay roll, while bonuses, commissions, etc., vary more directly in proportion to sales volume. The method of rewarding salesmen for the results they attain must be taken into consideration in establishing the normal for the several steps in the range of possible sales volume. Salesmen's expenses may or may not have any relation to sales volume, depending upon their plan of campaign. The extent to which an increase in volume of sales is a result of an increase in the volume of sales per invoice or an increase in the number of invoices would have a bearing on this and would indicate whether or not normal expenses for salesmen should vary in proportion to sales volume.

2. Supplies. This item is not large usually but is readily set up for the reason that supplies are inclined to vary almost in exact proportion to sales, at all events, an easy and obvious method of interpolating the normal values throughout the range of volume may be found.

3. Other. There are a number of miscellaneous items, such as postage, telephone and telegraph, autos and trucks, freight out, etc., the normal for which can readily be established according to the steps in the range of possible sales volume.

C. Charged Directly to Territories. Among those elements of sales expense which are wholly within and directly chargeable to specific territories we have warehousing, branch manager's office expense, salesmen's commissions where a salesman is confined to a specific territory, etc. Obviously these will be set up in normal exactly in the same manner as the distributed expenses, but they will be set up for steps in the range of territorial sales volume rather than in the range of total sales volume. Since the volume of territorial sales is less than the volume of the entire company, the problem is somewhat simpler but the same principles prevail.

The distribution of those elements of expense which are common to two or more functions or departments is adequately covered in the foregoing

paragraphs of this text and will not be repeated here. It is necessary to say only that such distribution must be performed for these normal values of these elements of sales expense in order to pass on to the next step of the summary of normals by functions or departments responsible.

Summary of Normals for Functions and Territories. *A. By Functions.* Following out the principle of expense control aimed directly at the persons, departments, or functions responsible, the normal values of expense must be collected according to departments and functions, which departments or functions are shown on the accompanying chart. It is necessary to collect the normal values of selling expense for each step in the range of sales volume under each of these departments or functions, and thus to secure total normal expense available for comparison according to the volume of sales realized.

This control of selling expense should be exercised each month, possibly in some cases as often as every week, and it will therefore be necessary to inspect these normals on a monthly (or weekly) basis. The main thing is to be able to compare the actual expenses of each functions with the normal expenses for that function for the period, and for the actual volume of work which they did.

B. By Territories. Still following the principle of aiming this selling cost control directly at the persons or functions responsible, it is likewise necessary to set up normals for the various elements of expense located entirely within a territory and under control of the territorial representative. Typical of this class of selling expense are the salesman's expenses, warehousing, branch manager's office, etc. These normals are set up in exactly the same way as the normals for the general office expenses by analysis of the sources of expense for each step in the range of possible sales volume.

1. **Salesmen's Expenses.** The most logical way of establishing a normal for this item is by analysis of the salesmen's routing and of the various items of expense, such as hotel, meals, traveling expense, entertaining, etc., according to their regular route of travel and duration of stay at the various points on their route. Just how this expense will vary according to volume of business will depend on a great many factors. It may be constant if the product and territorial conditions are such that the coverage is constant, or it may vary inversely with volume of sales if a salesman is expected to exert additional selling effort in times of diminishing business; or it may vary directly with volume if the company chooses to curtail expenses along with a decrease in sales. Whatever the conditions, it will not be a difficult matter to establish normals for this item of salesmen's expense.

2. **Branch Office.** The conditions under which the normals are established for the various steps in the volume of sales will duplicate to a large extent the conditions under which the normals are set for the central office expenses. In other words, there are clerks, stock clerks, handlers, and other personnel whose status is the same as that of the central office personnel, and the normal of this expense will be set up in exactly the same manner as the normal for the corresponding central office.

3. **Warehousing.** This item of expense is more apt to be constant than it is to vary with a change in volume of sales. If any change may be expected it will probably be a direct change for the reason that any change in the

volume of business incurs a corresponding change in the amount of its expense through an increase or decrease of space charges, labor costs, etc. The warehousing expense will more nearly approach a direct relationship to volume of sales than most items, and it is even possible that twice as much volume of sales will mean twice as much warehousing expense.

C. Application of Functional Normals to Territories. It has been pointed out how the expenditures of the several selling functions or departments may be controlled in total quantity through the use of the normal values for their expenses for the month or week. After this has been done there still remains the question as to whether or not the selling functions or departments have expended their energy not only in the right amount but in the right direction. By that is meant that a selling department may keep within its normal expense for a period, but still have expended too much time or money in one direction and not enough in another. This might be illustrated by the shipping department, which may have a monthly normal of \$500, made up of \$250 for the handling of merchandise going to each of two different territories. It is possible that the shipping department may have devoted an excess proportion of its time and expense to one of those two territories at the expense of the other, and when such an occasion occurs to any appreciable extent, it then becomes necessary to redistribute these departmental or functional normals to the several territories, so that we may have a measure of the performance of each department or function in terms of the territories, and perhaps even in terms of the various products within the respective territories.

This can readily be done by distributing the total normal of each department or function to the territories served in the same way that the actual expenses of the same department or function was distributed to the territories, as pointed out previously in this text. The bases of distribution are the same as were used in distributing the actual expenses, and the final results would be the setting up of normal for each function in terms of the territories served, and if it is desired to carry it further into the product within the territory, then, again, the same basis of distribution as was used for actual expenses may be adopted.

Considerable good judgment will be needed in deciding whether or not this is necessary, as it entails not only additional effort in setting up the normals, but also additional effort in distributing actual expenses monthly for comparison with these normals. While it is conceivable that it should be done, it must be kept in mind that the whole problem of selling expense control should not be weighted down with too much clerical and accounting detail.

Having established normals as measures of attainment, the next requirement is a simple and direct accounting procedure which will provide for the charging of all disbursements accurately and their distribution where necessary. The same bases for the charging of these expenses will be used as was used in establishing the normals in the beginning.

Accounting Procedure. Some of these typical procedures may be illustrated by three representative types of expense charging and distribution. Probably the simplest type of charge would be the salary and expense of a salesman operating entirely within one territory and, in this case, the salesman's salary and expenses will be charged to this territory. Another type of

expense is that of the traffic department, the total monthly expense of which would be charged to the various territories and products according to percentages representing the service of this department to the respective territories and products, in the same proportion used to establish the normals of expense for this department. Certain other types of expense should be charged individually, according to the territory or product which incurred this expense. Typical of this would be the expenses of the estimating department, where it is probably wise to keep time and material expense records for estimating on the individual inquiries, so that when all of this expense has been collected it can be charged against the territory from which this inquiry came. Obviously this should be done by the head of the estimating department on a regular form supplied for this purpose. This form should contain provisions for the number of hours of time expended by estimators at their regular hourly rate, for the various materials consumed in making the estimate, and for all other elements of expense incurred. When completed and charged by the chief estimator, this form would then be forwarded to the accounting department and charged against the territory and product to which it has been distributed.

There are, therefore, at least three types of routine expense and three types of corresponding methods of charging them, namely, the expense incurred entirely in the territory, the expense charged as a percentage of the total monthly expense, and the individual job expense charged directly. It should not be a difficult matter to decide upon the proper method for each of the elements of selling expense.

Since the internal routine of the accounting department for collecting and charging expenses is merely another application of well known accounting principles and procedure, it will not be necessary to go into that in detail here. It should be remembered, however, that a multiplicity of selling expenses, territories and products, need not operate to prevent a plan of selling cost control from functioning smoothly and accurately. After all, there are only three important things to be kept in mind, first to distribute normal expenses and charge actual disbursements upon the same bases and then to provide that the data flowing into the accounting department is clear, definite, and concise. This internal routine will depend to a large extent upon the form of the various monthly or weekly selling cost reports which the management desires. These we will take care of in the following paragraphs.

Cost Control Reports. In considering the set-up of reports which are to be the tangible instruments of cost control, it must be recognized that an almost infinite number of combinations of conditions may exist, and without assuming a set of conditions peculiar to a given industry and company it would not be possible in this text to outline in detail either the type of reports best suited or the method of compiling them. Only the important principles to be kept in mind can be pointed out, and the importance of making these reports as simple, direct, and effective as possible emphasized.

The main thing that should be shown on these reports are the selling departments or functions which we desire to control, the volume of sales or other indicator of the quantity of work each has performed, the normal expense corresponding to that volume of sales or work performed, and the

actual cost of operating that function for the period, together with the variances, plus or minus, and any explanations of these variances. These principles may be illustrated by a simple case of the billing department, against which would be shown an indicator of the work performed either in volume of sales or number of bills sent out, the corresponding normal expense, the actual expenses of that department (including all distributed expenses), and the difference, plus or minus, showing whether or not this department has been running as it should have run. Before this report goes to the executives for review and action all explanatory comments should be included so that the picture is complete and clear in all necessary detail.

In the case of a large company having two or more divisions, obviously there will be such a report for the head of each division, and all of these divisional reports will be combined into one report for the central executives.

It is probable in many cases that each individual department should have its report which contains considerably more detail than the report which summarizes the operations of several departments.

It must be recognized that virtually every individual company would have its own particular set-up in this respect and that each company must exercise its own judgment in deciding how far to go in detail on these monthly reports. Too much cannot be said in emphasis of the proper combination of simplicity for effectiveness and completeness of detail for usefulness.

Prevention of Cost Variances. The foregoing with respect to the subject of selling cost control mechanism has been largely curative in action. In other words, the expense report has been provided showing what happened and why. Such historical data is of the utmost importance and absolutely necessary, but there is a further valuable function that the program can and should be made to provide. It would be very desirable to prevent the occurrence of excess cost, and this selling cost control mechanism may be preventative in nature by placing the normal selling expense values in the hands of the department heads responsible, so that they may have before them at all times a guide which will tell them how much money they are responsible for. While this is not possible in some cases, it is entirely practical in others, particularly those functions whose expense of operation has a direct relation with volume of sales. It is suggested that the heads of such departments be supplied with the normal values set up for each of the steps in the range of sales volume, and then kept advised as to the trend in sales volume, so that they will know at all times what their expenses should be, they will have the means of adjusting these expenses at the earliest possible moment so as to keep them in step with the conditions of the business, and they can therefore be held properly responsible for their part of the entire picture. It hardly needs to be said that where this plan is followed out, these department heads should have played an important part in establishing the normals in the beginning, these normals should have had their approval, and they should be caused to feel the degree of their respective importance in carrying out the entire program.

It is probably obvious to the reader that the fundamental principles of the cost control mechanism outlined here are very similar to the principles which have been applied to the control of manufacturing costs. While the

application of these principles of standard costs to manufacturing is somewhat new and as yet not thoroughly perfected, nevertheless, they have attained considerable success and are widely recognized as the best available means of knowing and controlling manufacturing costs. Under these circumstances, it is no more than logical that the same principles may and should be applied to the selling activity and it is equally logical to assume that the same degree of success will be met in the field of selling activity. There have already been a few applications of these principles to selling, these efforts have met with considerable success, and it is believed that these results more than justify faith in further such application.

Some Uses of Selling Cost Data. After going through the analysis and distribution of selling expenses as described in the preceding pages, the accountant will inevitably learn many facts which will be useful to the executives in reducing selling costs generally, and in directing the activities of the various departments. It will be well, however, to suggest a few of the more important facts which may be learned, the knowledge of which has helped many companies to an increase in volume and a reduction of costs, and therefore to increase net profits.

Can Volume Be Increased without a Disproportionate Increase in Costs? This is undoubtedly the most important question which the sales executive has to answer. With the constant struggle for increased volume to keep factories operating at something like normal, there is grave danger of obtaining that increased volume at a cost that is in excess of a reasonable margin between manufacturing costs and selling price, even if the selling price itself is not reduced.

Knowledge of the cost of selling in each territory and by products will show how much the volume must be increased in that territory to produce a profit and at the same time will indicate how much it will cost to get that increased volume. There have been many instances of certain territories being abandoned altogether when the facts showed they were being covered at a loss.

Profitable and Unprofitable Products in Different Territories. Accurate knowledge of selling costs will also show which products are profitable and which are unprofitable in certain territories. Inevitably certain lines can be sold in certain territories with less effort and less expense than in others, either because there is a larger potential volume or because of competitive conditions. Without adequate cost knowledge there is danger of trying to increase the sale of certain products in certain territories just because it is thought the volume ought to be larger. Adequate knowledge of selling costs will bring out these facts and probably indicate how the situation can be improved. Even if it is considered good policy to continue handling these items at a loss, that will be done with full knowledge. At least it will be possible to restrict the proportion of the unprofitable items sold in any one territory or to any one customer.

Which Sales Method or Type of Organization Should Be Adopted? This question cannot be answered through a knowledge of selling costs alone, but obviously if more than one plan is followed in any one organization it will soon develop that one is less expensive than the other, and ways and means will be found to distribute the entire product in the most economical manner.

There have been many instances of companies finding out that methods which they supposed profitable were just the opposite, and as a result changed from selling agents to the direct representative plan, or from distributing through jobbers to selling direct to retailers or consumers, or to establishing or discontinuing branches, etc.

Should Branch Offices or Warehouses Be Established? Here again is a question which cannot be answered strictly on a cost basis, because the matter of service to customers enters in, and it is hard to measure that strictly in terms of dollars and cents of selling costs. On the other hand, cost is certainly a very important factor, and if the establishment of a branch office or warehouse means a disproportionate cost in distribution, something else must be done.

Even if it seems good policy to open a branch office or establish a branch warehouse to give better service, save delivery time and transportation costs, there is always the question of how much of the routine work should be transferred to the branch and how much retained at the home office.

Salesmen's Compensation. Detailed knowledge of selling costs is most useful in arriving at a proper basis of salesmen's compensation, or, to put it in another way, in seeing that each salesman gets a reward that is equitable as compared with all other salesmen. Volume of sales alone is not at all a fair measure, since there are many ways by which the increased gross profit which should come from the larger volume of certain salesmen is more than offset by his increased costs. Frequently this increased cost is not disclosed in the direct expenses but only through a proper analysis and distribution of the cost of the various service functions, and a realization of the "concessions" which certain salesmen make to retain the customers goodwill.

Minimum Sale. Many companies distributing a variety of small and inexpensive items are confronted with the rather troublesome problem of keeping down the number of orders per dollar of sales. An analysis of their orders shows that a very large percentage are for very small amounts, and analysis and study of selling costs disclose the average cost of handling orders through the branch or home office. Bringing these two facts together frequently discloses that a large percentage of orders are handled at a very distinct loss.

This is a condition that cannot be corrected immediately, but if every salesman is aware of the facts he can usually do something to improve that condition and decrease the number of orders which are too small to make it pay to handle them by themselves.

Use of Cost Data for Special Studies. The foregoing covers only a few of the more important questions which frequently arise. Through an analysis of selling expenses, the accountant or sales executive will immediately discover many ways to put this cost data to good use, once the facts are put before him. Furthermore, any department head or any salesman in the field will do a better job if he has some knowledge of selling costs and the effect of his activities on them.

Conclusion

It may seem to the reader that the analysis and distribution of selling expenses, and setting up the necessary control mechanism is a very compli-

cated and expensive undertaking. The same thing was thought about analysis and control of manufacturing costs some years ago, but experience has proven that in actual practice it is not nearly so expensive as it would seem, and that, in any event, it is worth all it costs. Companies that have learned something about selling costs have found out that the same thing is true of selling costs.

It should also be remembered that it has been necessary to describe every possible item of expense under almost every possible condition, and probably no one organization would begin to have all of the problems which are suggested in this chapter. If the accountant will start with an analysis of the more important items and control them, refining the procedure as the need indicates, the immediate value of the facts disclosed will be evident and it will be found that the effort and expense involved is much less than might be supposed and is very much worth while.

CHAPTER X

RETAILING

THE DEPARTMENT STORE

BY BISHOP BROWN, *Professor of Store Management, Research Bureau for Retail Training, University of Pittsburgh*; and IRWIN D. WOLF, *Secretary, Kaufmann Department Stores*

What the Department Store Is. The department store is the retailing center of the community. It is not one store but many stores divided into separate departments, each unit carrying many lines of merchandise and being held to account for its own profit and loss. The separation of merchandise units into departments is the origin of the name "department stores." The number of departments varies with the size of the store. The medium- and large-size stores contain from 100 to 250 departments.

The varieties of merchandise carried in stock are a distinguishing feature. In general, only stores which carry ready-to-wear, yard goods, and house furnishings are rated as department stores. The following lines are listed in a classification of merchandise adopted by the Controllers' Congress of the National Retail Dry Goods Association:

- Dry goods.
- Small wares.
- Men's and boys' wear.
- Women's and misses' ready-to-wear.
- Shoes.
- House furnishings.
- Miscellaneous.

Each classification is divided into as many departments as the store wishes to manage.

Location. The location of a department store is vital. If ideally located it stands on main traffic routes or at intersecting streets. It is situated so that crowds, which are essential to its growth, can reach it easily. And its general appearance must be sufficiently attractive to appeal to large numbers of people.

The grouping of many retail stores forms the retail district. This concentration is not only convenient for customers but is important to the store. Where different types of stores in the same price range locate near each other the benefit is mutual. The location of a five-and-ten-cent store close by a low-priced department store has advantages for both.

Store Architecture. The type of department store building should express the character of its business. It should be suitable to receive the clientele which it serves. In outward appearance stores show various architectural influences. The present trend is toward buildings of stability, dignified in appearance and with a minimum of decoration. The modern influence of set-back elevation and plain straight lines has already found its expression.

The Number of Department Stores. In a survey conducted in 1925, the Marketing Research Department of the Fairchild Publications estimated the number of department stores in the United States to be 4,015; their total yearly net sales amounted to \$3,904,884,000. This representation was in cities with a population of 10,000 or over.

NUMBER OF DEPARTMENT STORES AND THEIR SIZE*

* Reproduced with the permission of Fairchild Publications, Inc.

In his "Economics of Retailing"¹ Dr. Nystrom estimates the number of department stores in the United States for 1928 to be as high as 8,000, with a total volume of \$6,500,000,000. This includes stores in smaller cities with less than 10,000 population, and such stores as William Filene's Sons Co., Franklin Simon, Best & Co., and Chas. A. Stevens & Bros., which do not handle yard goods and which therefore were omitted from the Fairchild survey.

Indexes of Department Store Trade. The Federal Reserve Board, through the Federal Reserve banks, collects monthly reports from department stores as one aspect of retail trade. The reports from stores are expressed as indexes

¹ The Ronald Press Company, 1930.

and are influenced by changing price levels. The chief value of these reports lies in the indication of the trends which are developed by customer demand.

The following chart pictures the rise and fall of department store sales and stocks (adjusted for seasonal variation) from 1919 to 1929 inclusive.

FIG. 1.—Monthly movement of Federal Reserve Board indexes of department-store sales and stocks, adjusted for seasonal variation, 1923–1925 = 100 (Reproduced by permission of Fairchild Publications, Inc., from *Retailing*, July 15, 1930.)

The relation of stock to sales should be noted for the years 1920 and 1929 respectively. A decline in sales in 1920 left stores overstocked. In the effort to prevent a repetition of this condition, a hand-to-mouth buying policy began to develop which showed its increasing use in 1929.

The following table of indexes gives a comparison of sales of department stores in the twelve Federal Reserve Districts for 1929. It is interesting to note that in nine out of the twelve districts sales were higher in 1929 than in 1928. Even in December of 1929 sales were only 2 per cent lower than December, 1928, and at that point were greater than in any year preceding 1927.

Kinds of Stores. Department stores may be classified:

- a. According to volume.
- b. According to ownership.
- c. According to type.

Volume. For purposes of statistical comparison the Harvard Bureau of Business Research in its annual report of Operating Expenses of Department Stores for 1929, classified department stores as follows:

INDEXES OF VALUE OF SALES OF DEPARTMENT STORES BY FEDERAL RESERVE DISTRICTS (FROM 1930 "COMMERCE YEARBOOK")

NOTE. Monthly index numbers are not adjusted for seasonal variations. Comparison, especially for 1919 and 1920, are affected by change in price levels (monthly average, 1923 to 1925 = 100).

* Monthly average sales in 1925 = 100.

1. Department stores with net sales of \$2,000,000 or more.
2. Department stores with net sales from \$500,000 to \$1,999,000.
3. Department stores with net sales less than \$500,000.

With figures reported by these classifications, any store may compare its operating expenses with the reported expenses of stores in its own group.

Ownership. So many changes have taken place in department store management in recent years that classification falls into two main groups: independent stores, and chain stores.

Independent Stores. There are two subdivisions of this group. One is the independently operated store working entirely by itself. The other is associated in operation with other independent stores. Examples of the latter group are the Associated Merchandising Corporation, and the Cavanish Trading Corporation.

Chain Stores. This group also has two subdivisions. Both are centrally owned. The first is distinguished by associated operation, such as Gimbel's and the Hahn Stores, the second by central operation, such as Sears, Roebuck & Co.

As one of the conclusions from the data published in the 1929 edition of department store operating expenses by the Harvard Bureau of Business Research is found the following:

Comparison of centrally owned and independently owned department stores in each of the three divisions indicated that the former commonly operated with higher expense percentages than the latter. For the so-called chains with sales less than \$2,000,000 relatively large losses were sustained, 2.4 and 1.3 per cent of net sales for small and medium-sized stores, respectively. Similar stores with sales of \$2,000,000 or over were more successful, securing profits typically amounting to 0.7 per cent of net sales.

Small and medium-sized and independently-owned stores appeared to have lower total expenses when doing some group or central buying than when they did not use this method of purchase. Such firms either broke even or showed a slight profit. Large independently-owned stores, on the other hand, operated with lower expense and higher profit when not doing group or central buying.

Types of Stores. Stores are classified according to type as well as volume. There are promotion stores, prestige stores, and stores in between for which no name is generally accepted. The elements by which stores are distinguished are the following:

Price. Some stores develop a successful business on price appeal alone. Advertising and display emphasize the unusual value, the bargain, the extraordinary savings. Merchandise becomes a secondary feature; price is all important. Many stores are represented in this classification.

Quality. Quality is found where stores have insisted on certain maximum standards for merchandise. A generous adjustment policy usually accompanies rigid merchandise standards.

Service. Different forms of customer service distinguish some stores from others. Delivery systems, credit departments, adjustment departments are common. Shopping garages, free gift wrapping, theater ticket reservations,

and travel bureaus distinguish those stores which pride themselves on customer service. The perfection of this service and the work of the salespeople tell whether the store is to be marked as a service store.

Fashion. No matter what the type of store, fashion rightness is sought by all. Inexpensive merchandise quickly adapts itself to fashion changes. Some stores are more alert than others in sensing the trend and in having the latest fashion in stock. To anticipate the wishes of store trade is the art of merchandising.

Assortment. Whenever the unusual in size or color range is desired, there are usually one or two stores in every city to which customers turn. These stores have a policy of complete stocks. The opposite policy is to concentrate on fast-selling items.

The Clientele. Stores may also be classified according to the income groups which they serve. Only rarely are stores successful in serving more than two adjacent income groups. Quality and service, quality and style, price and style, are found together, but there are very few successful stores that aim at once at the high, medium and low price trade. The difficulty is to recognize the groove in which the store will operate most smoothly and show the greatest net profit.

Organization. Typically, department store activities are organized around four divisions—merchandise, publicity, control, and store management. Each division has its top executive, who reports to the head of the store. In smaller stores one executive may be responsible for the operation of more than one division; for example, the duties of control and store management may be combined, or of publicity and merchandising. In cases in which the head of the store takes counsel with divisional managers on general as well as specific problems, decisions so reached represent the opinion of general management.

The Merchandise Division. The function of the merchandise division is to buy and sell at a profit. The duties of the merchandise manager are:

1. To manage a group of selling departments.
2. To know market conditions.
3. To develop resources.
4. To control all purchases by an established budget.
5. To develop new selling lines and methods.
6. To follow up on slow-moving merchandise (sometimes called excess merchandise).

The Publicity Division. The publicity division includes all forms of store advertising. Newspaper advertising, direct mail, window display and public relations are all included under publicity. The function of advertising is closely allied with merchandising.

The Control Division. The control division includes all accounting and financial operations. The duties of the controller are expressed in

The receipt and disbursement of money.
The supervision of credit, collections, and audit.
The operation and control of budgets.

The significance of this position is not in the accumulation of statistics or records but in the interpretation of details which may be of general and far-reaching importance.

The Store Management Division. The functions of the store management division are more diversified than those of the other three. Because customer service is the principal problem of the store manager (also called general superintendent), he must be sure of the performance of every one contributing to the quality of this service. All personnel duties are usually under his control, and he is responsible for the efficiency of all employees, as well as for their morale. He superintends the purchase of supplies, protection against theft of merchandise by customers and employees, and maintenance and repairs. Successful operation of the receiving, packing and delivery departments are usually added to his work.

Problems of Merchandising. The function of merchandising is to buy and sell merchandise at a profit. Net profit depends in part upon the skill used in keeping the proper margin between the cost of selling merchandise and the selling price, and in part on the skill in keeping expenses in line.

Much of the guesswork which formerly existed in merchandising has been supplanted by facts. The sales plan has taken the place of snap judgment. The logic from accumulated data guides the instinct which at one time staggered unaided.

The science of merchandising, whether in a large or small store, is found in: Merchandise that is fashion right in the right quantities and assortments. Stock distributed in that proportion to sales which allows the entry of new merchandise evenly and regularly.

Merchandise that represents the character of customers of the store and is priced at the amount which they are willing to pay.

Advertising that brings to a store its daily share of buying customers.

Display that attracts customers and induces them to buy.

Service, in every division of labor, that expresses intelligence and training.

These are the easily recognized ear-marks of good merchandising, but in addition, horizons are being continually broadened with experiments in new lines of merchandise that will attract groups of customers comparable to the present store trade. This is called creative merchandising, and is usually profitable. As a merchandising problem it may be explained by the following illustrations:

Profitable merchandising swims downstream, with the current of consumer demand. The creative part of merchandising is the part played by a merchant when he discovers, with originality, precision, and imagination, which way the current is flowing. If hose at \$1.65 are selling faster than hose at any other price, that is the price which the creative merchant promotes. If radios are getting smaller, the merchant will not push the big ones; and at the same time he will provide small good-looking end tables on which to put the more fashionable radios. When reptilian leathers decline in popularity the creative merchant will stop buying them except in small quantities and will experiment with new lines to discover if he can what new leathers are taking their place. When a Lindbergh bridges two continents, alert merchants promote the symbol of his achievement in a goggled helmet for children.

Whenever a crowd gathers around an item of merchandise, the creative merchant brings that item to his customers in increasing quantities and throws the weight of promotion behind its assured acceptance.

The Merchandise Budget. The merchandise budget is a sales and buying plan which steers the buyer along the pathway of better buying. No careful buyer enters the market without an analysis of just what merchandise his customers are demanding and the amount of merchandise necessary to bring his stock purchases to the planned figure.

His first step is to budget or plan the sales. This is usually done in advance for a six months' period. By establishing sales objectives based on past experience and current business trends, it is possible to determine the amount of stock that will be required week by week and month by month. This estimate also indicates the amount of capital necessary for the same period. Careful planning of the sales and stocks for a department is necessary for the most satisfactory rate of stock turn. This is dollar control.

It is not only necessary to plan the dollar amount of stocks to be carried but the different price lines, colors, sizes, and other classifications, in relation to sales. Here again departmental conditions are observed—the volume trend, the fashion trend, consumer demand, and the stock on hand. This is called control by units, or unit control.

It is not an easy matter to determine the proper balance between stocks and sales. As a means of assistance, whatever form of unit control a store wishes to use should be brought into play to see that buying for the different merchandise classifications is carried out.

The formation of the merchandise budget takes into consideration such factors as planned sales, planned stocks, planned mark-downs and planned initial mark-up. The buyer receives from the controller's office the budget form to be made up for the coming season. It contains the experience for the same season last year, which is a guide for the buyer's planning. The beginning and the end of budgeting is the inventory figure.

The accompanying forms illustrate a merchandise budget and an outstanding order sheet which is used with it. (See Figs. 2, 3 and 4.)

First, the amount of sales is planned, at which time every force contributory to success or defeat is weighed. Changes in department location, expansion, contraction, style changes, local competition, comparison with similar departments in other cities, the growth of the store as a whole—these and other considerations influence the dollar amount of planned sales.

When the planned sales have been decided upon the right dollar amount of stock is planned to maintain these sales.

Unless initial mark-up is planned to include planned mark-downs, the gross margin may fall too low to allow a satisfactory net profit.

One of the outstanding advantages of a planned merchandise budget is found in the planned mark-down percentage. Formerly mark-downs were loosely taken. Because they are such an important factor in determining net profit a successful buyer scrutinizes the reasons for each one to prevent its recurrence. Whether the fault lies in imperfect merchandise, wrong fashion, inadequate selling, badly timed promotion, or poor advertising he plans to avoid mark-downs on that same score for the season ahead.

The planned initial mark-up is affected not only by mark-downs but by expenses and inventory shortages. When these three items are deducted from the total planned initial mark-up, the result is the planned net profit. This figure, the planned initial mark-up percentage, is often prepared by the merchandise manager, in cooperation with the buyer. Thereafter it becomes a standard percentage which the buyer applies to all his purchases. A common practice is to subtract the mark-up percentage from 100, divide the cost price by the remainder and multiply by 100, in order to get the retail price. For instance, hosiery is offered at a cost of \$12.00 per dozen pairs. With a mark-up of 40 per cent, subtract 40 from 100 and divide \$12.00 by the remainder, 60, which gives 20 cents, times 100 gives \$20.00. This gives a retail price of \$20.00 a dozen, or \$1.67 a pair.

FIG. 2.—Merchandise budget form.

Open-to-Buy. With a merchandise budget in operation, a buyer is able to tell at any time how much he can invest in additional merchandise. This is called open-to-buy. The open-to-buy figures are planned by the control department by weeks and months. In this way the buyer knows just how much he can purchase before he goes into the market. Formerly buyers knew only the total purchasing amount, but recent developments require a more precise knowledge of the proper distribution of units of merchandise, by classifications of size, color, material, etc.

Unit Control. Unit control is the method by which creative or downstream merchandising is accomplished. It is simply a way of finding out, and using,

[illegible]

FIG. 3.—Stock and order sheet.

the indexes of customer demand which are already available in the sales records of the store.

When the retail method of inventory was adopted, it became possible to control buying by means of the physical units of merchandise as well as by dollar amounts. Records of sales are analyzed in various ways, for instance by size, color, material, manufacturer, style, and especially by price lines.

This analysis informs the buyer in what proportions he should arrange his stock. If 35 per cent of his sales for the period of the analysis were made in pastel colors (assuming that he had offered a complete assortment of colors), then his new stock should contain approximately 35 per cent of pastel colors. If his trade is such that 20 per cent of his sales were made in outsizes, he should buy so that his stock will be arranged accordingly. If, in the rapidly changing fashions of the dress department, his sales ran high in novelty crepes, he should notice how far away the end of the season is and should estimate how many of these dresses he can continue to stock for his public.

FIG. 4.—Orders outstanding.

In many departments fashions change too rapidly to permit a rigid use of unit control. But the danger is usually that the buyer does not make sufficient use of the figures which are available to him, partly because he does not understand them, partly also because he is afraid that the controller, who collected the figures, is using them as a check on his judgment of demand. This attitude is mistaken. The controller's interest is in precise and profitable merchandising.

There are many unit control devices. The simplest form is a separate card for each type of merchandise. Source information, such as the name of manufacturer, price, and quality of the item is recorded. A perpetual inventory card can be made by listing the amount of merchandise on hand, additional purchases, returns *from* customers and *to* manufacturers and the amount of sales. The balance of merchandise on hand is always available for quick reference when a control of this kind is kept.

A more recent technical development in unit control is used at Kaufmann's, in Pittsburgh, in the ready-to-wear departments and in the Annex, and forms a part of the system of central records. In the latter plan the merchandise is marked by means of the perforated price ticket shown in the illustration.

At the time of sale the price ticket, together with a customer's card and the salesperson's card, is placed in an electrical transmitting machine and at a distant office the entire transaction is forthwith punched automatically on a Hollerith card, by means of a receiving device. The following are illustrations of the forms used in this system of unit control:

Perforated price ticket. (See Fig. 5.)

Customer's card. (See Fig. 6)

Salesperson's card.

FIG. 5.

Audited figures for these departments are available shortly after the store closes, and the analysis by different classifications is available on the following day. Supplementary machines even make out bills from the Hollerith cards. This is the highest mechanical development available for unit control today.

The plan and the installation may be expanded to departments other than ready-to-wear, but as its expansion proceeds to departments where low-price units prevail, its relative cost increases and its value therefore diminishes.

Its real efficiency, however, depends on the use made of it by buyers and merchandise managers.

Controlling the Merchandise Budget. The preparation of the merchandise budget is one test of the buyer's ability. If he has made mistakes in the past he will try to eliminate them; he will make an effort to duplicate successes. When he completes his planned budget he discusses it with the merchandise

FIG. 6.

manager. Changes are agreed upon. The controller interprets from department statistics tendencies which should be followed up or avoided. In its final acceptance the merchandise budget represents the pooled judgment of the best minds concerned with the problem.

Once in operation the buyer is guided by reports from the controller's office indicating the position of the department in relation to its budget. The buyer's weekly report is a common form in many department stores.

The merchandise budget is as valuable as its planning. The nearer planned figures and actual figures are in accord, the better the operating result. A

budget is only a guide. It should be elastic enough to allow for all changes in fashion and shifts in customer buying, and is frequently adjusted to current trends by the buyer and his merchandise manager.

Price Lines. As unit control developed in stores, retailers began to hear more and more about price lines. Price lining is a special aspect of unit merchandising. No matter how many prices are offered in any line of merchandise, the largest volume of sales will center around three or four prices. A store could offer men's suits with a long range of prices beginning at \$25 and growing by five dollar intervals to \$100. Thus it would have sixteen prices. But most of the business would be done at say \$25, \$40, and \$65, and the rest of the merchandise would stay on the racks.

This situation still exists, although it is disappearing. The many prices confuse the customer and result in large inventories and low turnover for the store. The salesmen have difficulty in explaining the differences in value between suits priced only \$5 apart.

E. A. Filene, in his "Model Stock Plan," advocates using only three price lines. Myron Silbert, in the "Buyer's Manual," suggests four.

The unit control analysis shows the prices around which the sales cluster. These prices, modified sometimes by a trading-up or a trading-down policy, are established as the price lines of the store, and 85 per cent of all merchandise in any given class is purchased to sell at one of the established price lines. The remainder of the stock can be purchased for experimental work in determining new demands in novelties.

The advantages of price lining are quicker turnover and greater net profit; less time needed for the buyer to select merchandise and train salespeople; a greater pulling power for advertising, because it can give a clearer picture of values; reduced operating costs in the marking room; and greater than any other advantage wide assortments in the chosen price lines, so that customer goodwill can be kept at an even grade by being able to find just what is wanted.

The Model Stock Plan. In every store, in every department, some lines of merchandise move more quickly than others; some sizes are in greater demand; some colors are in fashion for the moment. It is the buyer's responsibility to maintain as completely as possible the right colors, sizes, and assortments of fast moving merchandise. Obviously the proper price lines must be maintained as well. The model stock plan came into being through this need and where successful it has been the result of careful merchandise supervision.

As a means of building up his model stock plan a buyer should be as close to customer demands as possible. By observing the trade during the busy hours of the day, by training salespeople to report customers' preferences, and by using an accurately maintained want slip system, the buyer can have his finger continuously on the pulse of the trade. In this manner "duds" and slow-moving merchandise can be eliminated. But no amount of records can interest the department manager in promoting slow-moving goods nearly as much as handling those items physically.

A model stock plan needs constant supervision and revision. If no mistakes were made a model stock would be comparatively easy to organize and maintain. Many times the actual stock has become obsolete through

lack of follow up and weeding out, or because of too slow experimentation in new lines. The model stock plan is continuous, never ending, and should be developed around the lines bearing the greatest profit returns.

In the "Buyer's Manual," the following steps are given as a suggested procedure in setting up a model stock plan:

1. Divide the department into classification of subdepartments.
2. Divide each classification into individual items.
3. Establish the price lines to be carried in each item and set few price lines (these first three steps give a complete directory or "roll call" of the merchandise in the department).
4. Set the quantities of each price considering the time for delivery and turnover of each item.
5. Study the dollar amount in each classification (the total of all price lines in each item) to see that it is in line with its proportion of the total department's volume.
6. The quantity of each price line next should be subdivided into materials, sizes, colors, and styles.

After a model stock plan has been installed, efficient but simple methods should be used to keep it alive. Based on the rapidity of turnover and the time element in getting merchandise from the manufacturer definite minimums and maximums of stock levels must be set. Reordering in staple lines of merchandise can be carried on with no more effort by having well-trained personnel. The relationship between the sales department and reserve stock can be maintained in the same manner.

Embodied in a model stock plan is the unit control of size, color, material, style, and manufacturer. This includes a record of sales items by price. Where unit control is not practiced frequent inventories are taken. By comparing the inventory with the model stock the buying division is immediately informed of heavy stocks and also in which lines purchasing should be developed.

A model stock does not necessarily mean a large stock but in all lines the right proportion to sales. Rapid turnover in a few best sellers with other lines of the remaining stock stagnant or at low ebb will not create net profit. The evenness of turnover for the merchandise as a whole determines a successfully merchandised stock plan.

Turnover. Turnover is the constant changing of merchandise into cash and cash into merchandise. Whenever goods are purchased and sold the stock has turned. So has the capital invested. The more often stock is turned, provided an adequate mark-up has been maintained, the more often profit is earned. Likewise capital can be released to help out in other departments.

Because stock is never completely turned at once, turnover is the ratio of stocks to sales for any given period. The rate of turnover can be determined by dividing the net sales by the average inventory of stock at retail prices, or by dividing the net sales at the cost of the merchandise sold by the average inventory of stock at cost prices. The result will be the same in either case. The method used is determined by the store's accounting system; standard practice is the retail method. If a department sells merchandise at

retail amounting to \$50,000 for a period of six months, with an average stock of \$10,000, the rate of turnover is five times for the six months.

Relation of Turnover to Profits. Rapid turnover is efficient use of capital. If a buyer invests \$20,000 in merchandise and a stock turn yields a profit of \$1,200 he has earned 6 per cent on the investment. By turning his stock twice the profit is increased to \$2,400 or the yield 12 per cent. Operating costs will be increased in part but will not be doubled, for some expenses, such as heat, light, and rent, remain the same.

Disadvantages of Too Fast a Turnover. If all classes of merchandise in a department turn at the same high rate, the result is satisfactory. This is not, however, a common occurrence. Too frequently the buyer selects a small amount of merchandise which moves rapidly. Constant reordering adds expense to the cost of selling and results in the loss of goodwill because desired merchandise is not on hand. If the buyer ceases to order, hoping the balance of stock will move, volume drops in the slow process of forced or upstream selling.

RATES OF STOCK TURN FOR VARIOUS SIZES OF DEPARTMENT STORES
From the Harvard Bureau of Business Research

Net sales of less than \$500,000 (1929)

	All firms	Less than 2.0 times	2.0 to 2.9 times	3.0 times and over
Times a year.....	2.4	1.6	2.4	3.6

Net sales of from \$500,000 to \$1,999,000 (1929)

	All firms	Less than 3.0 times	3.0 to 3.9 times	4.0 times and over
Times a year.....	3.3	2.5	3.4	4.6

Net sales of \$2,000,000 or more (1929)

	All firms	Less than 4.0 times	4.0 to 4.9 times	5.0 times and over
Times a year.....	4.2	3.2	4.2	5.7

Problems of Advertising. Two sets of forces are continually at work to sell merchandise: the external force of advertising as found in newspaper, direct mail, radio, billboard and street car advertising before the customer enters the store, and the internal force of good salesmanship when customers come in to

look and remain to buy. Advertising is as essential to the average department store as light and space. In whatever form it takes, the whole purpose of advertising is to create an interest in the merchandise and an urge on the part of the customers to go to the store to see it.

Two recent tendencies in advertising are important. The first emphasizes value in use, that is, advertising the merchandise as it will appear in the customer's home, or as she wears it, rather than stressing some difficulty involved in manufacturing it or the splendor of its source. An example of this is taken from the chatty advertisements of R. H. Macy & Co.: "High chairs at low prices . . . A Windsor back, maple-finished colonial chair that gives a baby that Early American feeling." The second is closely related to the first but stresses the added beauty in the home, or the improved appearance of the customer, which is to result from the merchandise in question, always using an emotional appeal. For instance Saks Fifth Avenue says: "Pearls, rose-tinted, the classic and most flattering of all jewels." The success of the advertiser is measured by his ability to make the merchandise seem real and interesting before the customer actually sees it.

Cost of Advertising. The cost of advertising for stores having net sales of less than \$1,000,000, according to reports of the Harvard Bureau of Business Research, was 2.1 in 1922. This compares with 2.5 in 1929. For stores with net sales over \$1,000,000 the cost was 2.9 in 1922 and 3.4 in 1929. This increase in advertising cost, which applies to all stores, is due to the pursuit of volume which has been the great driving force in retailing during the past decade.

The amount of money which a store spends for advertising depends on the sales volume, on the type of store, on the kind of merchandise carried, and on store location. Some kinds of merchandise are more expensive to advertise than others. Staple and convenience merchandise must maintain a low advertising cost while fashion merchandise, such as ready-to-wear and costume accessories are usually subjected to greater advertising expense. In some nationally advertised lines, such as radios, mattresses, and washing machines, the manufacturers subsidize advertising costs during store-wide promotions and anniversary sales.

Advertising Budget. In order to supervise the ratio of advertising expense to sales a control in the form of an advertising budget is set up. Every store hopes to get definite returns for every dollar it spends in advertising. Unusual weather conditions, poor advertising, the wrong choice of merchandise, and other factors may prevent the expected result. Some stores maintain a follow-up on returns for different kinds of advertising. Such information determines the allotment of space to different lines.

The amount of advertising expense may be determined in part by local competition among different lines and in part by arbitrary allotment of advertising expense to planned sales. In many cases the cost is definitely set up as a fixed per cent of sales based on previous experience. Adjustments are made to meet local conditions or to swing into a new and rapid merchandising promotion.

Like the merchandise, expense and other budgets, the advertising budget covers a six months' period. It is developed through daily and weekly

schedules by estimating costs which are based on advertising plans. Holidays, local anniversaries, and any events around which advertising can build a selling campaign must be factors of the plan. Fashion advertising is always in advance of the season, allowing opportunity to feature individual models usually starting at higher prices. When the season is in full swing sales momentum is carried to medium prices. By this method the right proportion of advertising expense is allotted to closing out seasonal merchandise at low or bargain prices. The trend not to advertise clearance merchandise is becoming more and more apparent.

Total year				

Newspaper Advertising. Newspaper advertising is used most commonly by all department stores. Rates are based on the amount of lineage used during a year and preferred location depends on the amount of daily space

in that issue. Because the second and third sheets of a newspaper are believed to be read by more people than the pages that follow, some stores endeavor to identify themselves with the public by always using those pages. Likewise right-hand pages and the first and last pages of sections are regarded as choice positions because they are seen with little effort.

Direct Mail Advertising. Direct mail advertising is used to inform the clientele individually of important offerings. This method is being developed more intensively by some stores. Different kinds of merchandise are promoted among selected customer groups who either have indicated interest by previous purchases or who are desirable as prospective purchasers. Names are obtained from mailing lists of various organizations, directories, and school lists. Some lists are highly specialized for merchandise appeal, such as Boy Scouts, automobile owners, new home owners. In comparison with newspaper advertising direct mail is a more expensive form but it has the advantage of being placed in the hands of a definite number and class of individuals.

Other Advertising Media. Radio, street car signs, billboards, electric signs, and other types of advertising are of less significance. Of these, radio has hitherto unmeasured possibilities, for few measurements of radio advertising have been taken. In some instances it has been discontinued because the expense did not warrant the return; in other cases the stores owning and using broadcasting stations appear to have been satisfied with the results.

What to Advertise. Advertising is the reflection of store character just as is the opinion of any individual. If a man can be judged by what he reads, a store can be judged by its advertising expression.

All stores have one thing in common to talk about, and that is merchandise. But the advertisement expresses the type of store. On the one hand, price appeal and dollar amounts in black type dominate copy and cuts; on the other, the ideas and illustrations emphasize fashion *motif* and detail. Again, quality is the appeal, or the service and conveniences by which the store excels others.

Institutional advertising sells indirectly by pointing out the store's position in the community, its position of leadership in fashion promotion, its age, its high employee morale. It is frequently believed that institutional advertising for department stores is egotistic and is appreciated more by the owners than by their customers. Another view is that every merchandise advertisement has an institutional character, inasmuch as it contributes to the general impression of the store in the mind of the public.

Advertising layout or form should be attractive so that it is good to look at. The use of boxes, borders, cuts, white spaces, and copy should blend harmoniously. The typography should be carefully worked out, using the most delicate type faces to advertise feminine apparel, the stronger type faces for merchandise for men, and the faces in between for neutral merchandise like furniture. It should tell the facts straightforwardly and in enough detail to excite buying interest. It should be timely, taking advantage of current news interest. Above all else it should be wholly truthful. Recent surveys indicate a growing disbelief in the public mind regarding the tremendous savings continually offered. Care should be used to avoid overstatements.

Problems of Store Management. The problems of store management appear as receiving, checking and marking, delivery, customer service, maintenance and construction, personnel activities, operation, protection, and purchasing of supplies. Complicated situations arise from any one of these divisions of labor, but the store manager's major tasks are service and personnel.

To control the machinery of human relations between the customer and employee successfully requires an executive of greater capacity than is often recognized. The successful store manager is a well-rounded individual. He has the buying instincts of a merchant and the prudence of a controller for he must keep the store well for the customers without spending too much money. With an engineering sense of exactness he determines the right and wrong of the store's physical appearance, and prevents store system from becoming complicated and ineffectual. He sees the store objectively as a customer and subjectively as an operating executive. And with all that he has the patience to understand and like people.

Receiving, Checking, and Marking. The receiving of merchandise, checking it for quantity and marking the retail price is an operating responsibility of the store manager. The amount of space available and the number of freight elevators may determine the location of the receiving and marking rooms. In some stores they are located in the basement and in others on the top floor. Bulk merchandise, in carload shipments, is frequently delivered to a warehouse.

After merchandise has been signed for, opened, and examined, it is checked against the invoice. Two systems are in use, the open and blind check.

Open checking is a comparison of quantity and kind of merchandise with the amount and description on the invoice.

In blind checking all merchandise received is listed. Later, invoice clerks compare the lists with invoices. The latter system is being more generally used.

Because garment sizes vary some stores have adopted standard models for pre-sizing as many ready-to-wear purchases as possible. Inaccuracies of this sort, as well as imperfect merchandise, have been detected before customers were inconvenienced. Pre-sizing and inspection are usually a part of receiving room routine.

With incoming shipments such traffic problems as the form of transportation to use, the cheapest or quickest routes, and claims on short shipments or damaged goods are bound to arise. The return of merchandise to manufacturer, and supervision of the warehouse are also operating functions of the store manager.

Merchandise is marked by string tickets, gum labels or pin tickets. String tickets and gum labels are put on by hand as well as interlocking pin tickets which are attached to such merchandise as millinery. Price tickets contain such information as retail price, manufacturer's number, season letter or date, and size.

Wrapping, Packing, and Delivery. As merchandise is sold, it must be either attractively wrapped for the customer to carry, or securely packed for delivery to the customer's address. Smaller packages are wrapped at bundle desks by

young girls called inspector-wrappers. They inspect merchandise for imperfections and examine the salescheck and price tag for errors.

Parcel collectors relieve bundle desks of packages which are to be delivered. All packages not too large which have been wrapped for delivery are dropped down spiral chutes or taken down merchandise elevators to the delivery department.

In larger stores, a central wrapping room serves the entire store in preparing merchandise for delivery. Street-floor departments are particularly in need of this type of wrapping service. As an alternative, merchandise can be distributed to bundle desks in less busy departments for wrapping. During store-wide sales, this service cannot be depended upon.

In the race among stores to excel each other, gift wrapping has developed as a gilt-edge type of customer service. Wrapping and packing cost for ordinary bundles extends from 3 to 15 cents per unit, depending on the size of the article. Gift-wrapping costs are known to extend from 10 to 75 cents, depending on the quality of the box, cut paper, wrapping paper, and ribbon used. Wage cost is higher in the latter case, because of the care and skill necessary to do an acceptable piece of work.

The packing department can be the cause of many delivery complaints if improperly organized and managed. Engineering precision may be seen in labor-saving, time-saving, and well-lighted packing rooms. Waste motion is reduced to a minimum; waste in packing supplies is prevented by the use of a minimum number of box sizes. Boxes, excelsior, filling, and cut paper, salvaged from the receiving room, reduce packing expense. Improved time schedules and wage and bonus payment plans for packers have contributed to the efficient management of this department.

The National Retail Dry Goods Association, in its 1931 report of the Store Managers' Division, has provided a valuable check list of simplified sizes of wrapping and packing supplies. This operating expense in a store can be reduced by comparing its list of supplies with the recommendations which this report contains.

Retailing for April 25, 1931, reports that the Jordan Marsh Company saved \$110,000 in 1930 packing and delivery costs. This was accomplished by "an extensive relocation of wrapping stations, a change in the mechanics and routine of the central wrapping, the organization of a plan for measuring production of the packers, a more scientific analysis of inside delivery and a replanning of delivery routes."

Prepacking, or factory packed merchandise ready for retail distribution, has been a recent development. China and toys are types of merchandise which lend themselves to this arrangement. This method eliminates dual packing at the factory and store, cuts down receiving- and marking-room costs, speeds up delivery, reduces customer complaints on volume merchandise, and is obviously a saving in operating cost. Only samples of such merchandise are shown on the selling floors.

Free delivery service is generally expected of a department store. In order to build volume, stores have found it necessary to reach as many suburban districts as possible. Deliveries are common for a radius of 20 to 40 miles from the store. A large store can operate its own delivery organiza-

tion. In addition, parcel post and local express companies supplement store delivery. The small store, with many jumps between deliveries over a wide radius, must confine its own delivery system to localities in which its clientele is most thickly settled.

Cooperative and consolidated delivery systems are separate organizations which deliver merchandise for a group of department stores. Under the cooperative plan, two or more stores operate a delivery system which eliminates duplication of cost for the same effort. The Associated Retailers, Delivery in St. Louis, owned by four leading department stores, is an example of cooperative delivery. The Eleto Company in New York, which formerly served Lord & Taylor and James McCreery & Company, is another.

Consolidated delivery systems are independent organizations which deliver for department stores under contract. The United Parcel Service Company is an outstanding example. It handles all the deliveries for the important stores in Portland, Seattle, San Francisco, Los Angeles, and other western-coast cities. Recently, it purchased the Eleto Company of New York.

Some recognition of the delivery problem is apparent in the number of bundles handled. In 1930, the Jordan Marsh Company delivered over 3,000,000 bundles. This figure does not include furniture and large house-furnishings articles.

From December 1 to December 24, 1930, Macy's wrapped, packed, and delivered 1,953,647 items. This figure includes furniture as well as smaller pieces.

Unit delivery costs vary in different cities. In Pittsburgh and Seattle, steep hills add to operating costs. More than one delivery a day affects the total cost. It can be said generally that, for the country as a whole, the unit cost is close to 15 cents. According to the report of the Bureau of Business Research of Harvard University, the delivery expense to percentage of sales for department stores with net sales of \$2,000,000 or more is 1.25.

Customer Service. Customer service depends upon the shopping conveniences which the store offers and upon the personnel who represent the organization. Department layout, elevator service, ventilating systems, adjustment bureau, telephone order service, and delivery are some of the conveniences upon which a store builds goodwill. The following list indicates the wide variety of services offered. Not all are used by any one store, although many of the larger stores offer the greater part.

List of Shopping Conveniences

- Fashion magazines.
- Printed matter, stuffers, on services.
- Telephone order board—free toll service.
- Charge accounts.
- Garage—bus to store, chauffeurs' stand.
- Door service.
- Umbrella checking at door.
- Post office.
- Telephone booths.

Telegraph office.
Travel bureau or Ask Mr. Foster.
Paris office.
Escalators.
Refrigeration for ventilation.
Exhibitions.
Lectures.
Lost and found.
Parcel room.
Rest room and waiting room.
Drinking fountains.
Appointment book.
Santa Claus.
Gift wrapping.
Personal shopping bureau.
Fashion service—models, fashion parade.
Budget service.
Medical treatment.
Lost pocket book—money loaned for carfare.
Interior decorating.
Delivery service.
Valet service for men.
Reminders for anniversaries, birthdays.
Keeping store open for men in evening.
Returned goods.
Alteration rooms.
Cutting and fitting.
Hemstitching and picoting.
Hosiery repair.
Bow making.
Stamping linen.
Dry cleaning.
Repair work of all kinds—jewelry, rug, leather, etc.
Beauty salons.
Children's barber shop.
Men's barber shop.
Fur storage.
Restaurant and tea rooms.
Children's menu.
Children's parties.
Bridge parties.

Operating expenses have shown such a constant upward rise in the last few years that the trend to reduce the number of customer services is noticeable.

Layout. Careful attention must be given to the use of space and the layout of departments. It has been observed that customers turn to the right when entering a store and after a short time turn to the left. To meet this natural circulation of customers diagonal traffic lanes are a feature in some stores and are on the increase. The more conventional treatment consists of long parallel aisles with tables at right angles.

Merchandise which carries the greatest relative volume gets the preferred position on the floor. Appearance must be kept in mind and only the more attractive merchandise given prominent display. Convenience merchandise

is easily accessible, rarely changes position, and is usually on the first floor, which is devoted to quick selling merchandise. The second and third floors are usually given over to ready-to-wear, and the upper floors to more bulky items such as furniture and home furnishings.

Although the tendency has been to merchandise women's wear on the second floor and misses' ready-to-wear on the third, the trend is to locate all coats, both women's and misses', on one floor and all dresses on another.

FIG. 8.—First floor plan.

This allows for closer interselling to customers whose size is on the border line.

Elevator Service. Quick and comfortable transportation from floor to floor adds to the value of every floor above the street. To determine whether a store has a sufficient number of elevators is an internal traffic study which must not be neglected. A constant distribution of traffic is maintained when cars are lifted on even schedules. This is the duty of the elevator starter. In some stores timing by electric signals has speeded up this service.

In spite of the multitudes of customers moved from floor to floor accidents are almost nil. This is due to constant supervision of machinery and care used in training operators not to overload cars.

Escalators are an aid to traffic flow. While formerly they were used from the first to second floors, more and more this service is being extended to include all floors. In some stores as many as three sets of escalators are distributed across the building. Supplementary escalator service makes shopping almost as easy on one floor as another.

Ventilation and Refrigeration. To operate successfully department stores not only want but need crowds. One of the problems that large numbers of people create is that of ventilation. Fresh air is used up quickly. Customers become fatigued and restless. Salespeople grow dull and lifeless. The problem exists in summer and winter.

Many stores have already installed circulating air systems. During warm weather air is washed, cooled, and circulated. In cool weather fresh warm air is kept in motion. At present this plan is confined to basement and street floor levels. As one of the advantages that a large store offers over a small one this customer attraction will undoubtedly be extended.

Adjustments. In many cases store managers have given little or no attention to the adjustment department. This is partly the result of trying to run the department too economically. The adjustment manager is often a generous host who gives the customer what she wants because both he and she know that she will get it anyway. Then he forgets about it.

A change in the policies of this department is being anticipated by carefully managed stores. To the adjustment office flow problems which have come from individual mistakes, from bad store policy, or from no policy at all. The position warrants the rating of assistant store manager. In a small store the adjustment manager may be the understudy for the store manager. The newer interpretation of this position is not only to adjust customers' complaints but also to utilize them in correcting mistakes and in revising store policies and procedures.

Personnel. As an integral part of customer service the personnel of a store constitutes the second major problem of the store manager. A personnel department is essential to select, place, train, and follow-up whoever is hired. It is now more generally recognized that this division of labor is highly specialized and more attention is being given to securing a trained personnel staff.

One of the major difficulties in building a strong personnel for the whole store is the lack of written personnel policies. Management is usually reluctant to express itself about human relationships and often fearful of being embarrassed by previous decisions. Consequently where no policies exist, employment and training have no long term plan by which to steer constructive effort.

The remedy for this situation rests on the willingness of store management to recognize the importance of personnel administration and to follow its operation as consistently as any other function. One of the most expensive practices which department stores are now experiencing comes from high executive turnover. This is due in part to a lack of explicit personnel policies.

Buyers and other executives are hired arbitrarily by the executive offices without any reference to the personnel division. And yet for all other positions applicants are hired by definite and accepted procedures. It is clear that more care should be taken in employing for such positions as buyers whose turnover costs between \$10,000 and \$50,000.

A factor in the improvement of personnel management is proper induction into the job. Where executives are suddenly thrust into a position with no reference to the usual channels of employment and training they are obviously handicapped. They know neither the system nor the methods of obtaining assistance, and immediately mistakes of system and operation become a source of irritation and misunderstanding.

Where the rank and file are given no formal induction, due to inefficiency in the personnel organization, the employees are again left to flounder. In either case turnover is prevented only by unusual ability on the part of the individual.

A successful personnel job in a store can be measured in various ways. When a high rate of turnover is broken down into the different reasons for leaving, poor selection, inefficient training, lack of promotional opportunities, and other factors of employee well-being are brought out into the light. The morale of an organization may be high or low according to lack of interest in employee demand or the practice of minor injustices. Store managers are becoming more concerned in the quality of store morale by the adoption of well-thought-out personnel policies.

Every employee wants a chance to earn a living. Beginning wage scales should move forward as a man or woman proves his worth. Periodic salary and personnel reviews on a six months' basis meet this situation. No one has respect for the organization that underpays and it is apt to lose in community goodwill. On the other hand, there are maximum salaries for every job. A store cannot overpay and live. A low salary for a person of long service is expensive, and inefficient people discovered only after years of service are hard to discharge. The periodic review considers all these problems.

Training on the job and training for promotion are considered necessary to maintain a well organized store. Where all top executive positions are filled with sons and relatives, the middle strata is often filled with mediocre men.

The development and use of production and personnel records, both for employees and executives, are the most tangible methods of proving the worth of personnel organizations.

Problems of Control. The fourth and last major function of the store is control.

The history of a store is written into the accounts, statistics, and records that are gathered under the watchful eye of the controller. Ledgers may contain only black and red figures but in them is condensed the story of every executive in the organization.

To the controller falls the task of keeping the records and interpreting them for the executives. During the last ten years the controller has had an important rise in influence, partly because of increasing pressure to make merchandising and storekeeping precise and partly because he was often the only one in the store who understood the compilation and use of figures, the

sole instruments of precision. Control work has been accomplished most successfully in stores where the controller was not only an accountant and a statistician, but also had a strong merchandising sense.

In general there are three main divisions of the controller's work, accounting, budgetary control, and the supervision of finances.

Accounting. Under the head of accounting can be classified the following necessary store-wide functions:

Auditing.	Accounts payable.
Cash receipts.	Balance sheets.
Accounts receivable and credit.	Income statements.

In performing these functions the controller organizes his staff for accuracy and speed. If the figures are inaccurate they are of no use to anybody, and if they are too long delayed nobody in the store can make the best possible use of them.

The credit department with open accounts and collections as balancing activities is one function of the control division. What proportion of a business shall be made up of charge customers depends upon the financial structure of the organization. In some stores charge accounts run as high as 85 per cent of the total business. It is not so much a ratio of charge to cash sales as it is a question of efficient management.

The personnel of the credit department contacts daily with customers. They can act in a purely functional manner or become an important selling department of the store. The most successful credit departments are those which take every opportunity to promote goodwill for the store, whether in opening accounts or collecting outstanding indebtedness.

Recent developments in the field of electric accounting machines and control indicate that in the future accounting will be accomplished increasingly by these methods. Figures should be interpreted and presented as facts on which decisions should be made. Control, however, since it involves not only the compilation but also the interpretation and use of these facts, cannot be done by machinery, and will continue in the hands of the controller, at least until he has trained merchandise managers, buyers, and store operating executives to interpret and use the figures as well as he can himself.

Budgetary Control. By his knowledge of the facts the controller becomes the diagnostician for every division and every department. He may know little about the merchandise or the advertising or the technical details of storekeeping (although he should know a great deal). His function is to provide all divisions with information about themselves, in such form that they can use it quickly in determining their position with relation to their planned estimates, or in adding up their final results.

He works through two sets of information. One is the budget, the other the operating statement. Each division has its budget, prepared with the controller's help and advice, usually from last year's figures. Planned sales, mark-ups, mark-downs, stocks, and other information of importance are sent from the department managers through their divisional managers to the controller, where they are accumulated and used as a basis of reports, statements, and statistics.

Once accepted, these budgets (for merchandise, advertising, and expense) become the guide for the next six months' operation. They are modified as the situation requires and are never regarded as more than a guide. Until

modified, however, executives are expected to live up to them, and the controller throws his influence in this direction by issuing reports of operation. Each week the executives receive not only reports of their stocks, sales, commitments, mark-up, pay roll, and other expense, in accordance with the plans, but also certain supplementary reports, such as the unit control records of sales by units or pieces, and reports of slow-moving or excess merchandise. These records permit the department executives to arrange their activities so that the plans are more nearly met, and to take advantage quickly of any special purchases of merchandise that are discovered. The weekly reports are of the greatest importance to the store manager's division, for slight fluctuations of business in either direction can, if he is ignorant of them, make serious differences to his expense showing.

In some stores the responsibility for advising department executives of their shortcomings, and for counselling them on better methods, is assigned to the controller; in other stores his function is solely to inform, not to advise.

Samples of merchandise budgets are found elsewhere in this chapter.

A typical expense form is shown on page 300.

THE CHAIN STORE

By JAMES L. PALMER, *Professor of Marketing, School of Commerce and Administration, University of Chicago*

The extensive application of the chain idea to retail distribution in my opinion has had more significant and far-reaching consequences than any other single development in the field of marketing in the last two decades. It has created entirely new problems for manufacturers, wholesalers and retailers; has forced the adoption of new methods of marketing; has compelled practically every agency engaged in distribution to exhaust its every resource to reduce its costs and improve its methods of marketing; has brought about a wholesale elimination of such agencies as have been unable to meet this new competition; has brought into being an endless number of experiments in distribution which under the old order would never have been conceived; has in no small number of cases resulted in a decided shifting of the balance of power from one agency to another; and has set many people to wondering just what the phenomenal growth of this new industrial giant, the chain store, will in the next decade or two mean to them.

Speculation as to the future of the chain store and the probable effects of its growth upon manufacturers, wholesalers and independent retailers is to be heard in every quarter. Opinions have been expressed which are as far apart as the poles. To some the peak in the expansion of the chain store has practically been reached, and it will be unable to develop outside the relatively small field in which its methods have to date been proved successful; to others, equally well informed, it is but an infant in the swaddling-clothes stage, and will in the near future acquire control of 90 per cent or even all of the retail trade of this country. Few, if any, of those who have speculated upon the future of the chain have based their speculation upon a solid foundation of fact and analysis. This will necessarily continue to be the case until

far more exhaustive studies of the economics of chain store distribution have been made than have yet been attempted.

A "chain store organization" is any group of retail outlets centrally owned and managed. Whether the group be engaged solely in retailing, or be operated by a manufacturer, wholesaler or mail-order house does not matter. We exclude, however, the vast number of organizations that are in reality cooperative associations, whose members are grouped for buying or selling purposes, but in which for the most part management and ownership are decentralized.

Factors Favoring Chain Growth. In the past decade or two a number of *social and economic developments* have favored chain store growth. These seem to me to have been as follows:

1. Increasing density of population, and the migration from the farm to the city.
2. The depression of 1921 and the stress upon economy which it created for many.
3. The increasing thriftiness of our population and the resulting emphasis on economy in the purchase of goods.
4. An improved standard of living, together with the growth of installment buying. People have come to desire many things and have been forced to economize in the purchase of each in order to secure all.
5. The growth of wasteful and expensive marketing practices, and particularly the widely prevalent indifference of small retailers toward efficient operation.
6. The mechanical perfection of the automobile and the motor truck, resulting as it has in the solution of the transportation problem both from warehouse to store and from store to consumer.
7. The decline of the personal relationship factor in trading, due largely to the character of living conditions in urban centers.

The chain type of retail organization seems often to have certain *advantages in operation* over its independent rival. Among these are the following:

1. Greater skill in management due to the greater opportunity for specialization.
2. Greater financial strength and power in buying.
3. The possibility of using certain advertising media which are not adapted to the needs of independent retailers.
4. The possibility, through large-scale operation, of developing a prestige such as the average small merchant can rarely cultivate.
5. The ability, through integration, to eliminate selling and buying costs which are inevitable when manufacturers, jobbers and retailers are separate entities.
6. The ability, through integration, to coordinate production, wholesaling and retailing, thus lowering costs.
7. Possibly the ability to secure a more rapid stock turn than can most independents. Whether this advantage is inherent in the chain type is open to question.
8. Ability to make every unit profit from the experience of every other.
9. Wider distribution of risks than has the independent.
10. Ability to dispose of salvage profitably.

A third major explanation of chain store growth is to be found in *management efficiency and the selection of management policies*. Whatever be the

underlying causes, chains have unquestionably been more intelligently and aggressively managed than have most independents. This has been demonstrated conclusively in many different directions: buying, merchandising, selection of merchandise, adaptation to market demands, selection of store locations, etc. In addition to this, chains have concentrated upon policies which point directly to net profit. They have simplified lines, reduced stocks and increased rate of stock turn. They have eliminated service frills and have been content to cater to the demands of those consumer groups whom they could serve cheaply and yet profitably. They have concentrated on volume locations and have left the second-rate locations to independents. They have added new lines of merchandise whenever there appeared to be a possibility of profit in so doing. The conglomerate appearance of the modern drug store is no doubt due in part to the merchandising vision of the chain. If I were to present in one sentence an explanation of the rapid growth of chains, it would be this: *The success of the chain store has been made possible by favorable social and economic conditions, and is directly due to greater efficiency in management than independent retailers can in the nature of the case usually display; advantages in operation, inherent in the chain store type of organization, have been a factor, but probably not the major one.*

Much of what has just been said applies also to the growth of *manufacturers' and mail order chains*. However, a few added comments are in order. The growth of manufacturers' chains is probably due primarily to the difficulty encountered by manufacturers in securing satisfactory retail distribution of their products in any other way. The growth of the independently owned chain, the keenness of competition between manufacturers and between retailers for the consumer's dollar, the widespread inertia and inefficiency of retailers and the diversified character of the average retailer's business all help to account for the tendency of manufacturers to establish their own outlets.

Such success as the mail order houses have had in their chain store experiment is undoubtedly explained in part by the peculiarly favorable circumstances under which each of these enterprises was launched. Each company already had an enormous mail order business, with its merchandising facilities and contacts already established. Each had its various warehouses from which it could economically distribute to its stores as well as to its mail order customers. Each had a commercial prestige and goodwill perhaps unrivalled in magnitude and depth by any other organization in this country.

Under What Circumstances Have Chains Been Most Successful? In the first place, chains have met with some success in practically all retail lines. Their greatest success has probably been achieved in groceries, drugs, cigars and tobacco, shoes, variety merchandise, and gasoline and oil. In each of these trade groups but one, the retailer serves primarily as a transfer agent. He has occasion to practice very little real salesmanship. The amount of skill and knowledge he must possess is on the whole slight, and he is rarely called upon to serve as consultant to the consumer. Merchandise is for the most part standardized, and quite typically packaged. It is seldom perishable. It is for the most part capable of being turned over rapidly if sensible buying and merchandising policies are pursued.

In the grocery trade, and in considerable measure in drugs, tobacco, and gasoline and oil, the number of retail units is large and their locations close together. Hence it is possible for chains to take over their own jobbing function and to reduce costs in its performance. In groceries, drugs and tobacco products many items can be produced on a relatively small scale. Margins between the manufacturer and jobber are frequently high, hence the opportunity and urge for control of production by the chains. The conspicuousness of chains in the shoe trade is probably due primarily to the desire of manufacturers to control their own outlets—the fulfillment of which is made possible by the character of the shoe trade structure. In most other lines in which the chain has appeared it has had either a moderate growth or has had questionable success in earning profits. In practically all of these lines one or more of the circumstances above enumerated have not been present. Turnover possibilities have been slight; a high degree of skill and resourcefulness has been necessary in the retail store; servicing has been required; products have been unstandardized or highly perishable; or retail units have been widely scattered and hence inaccessible for purposes of delivery or supervision.

The hardware trade is an excellent illustration of a class of retailing in which the chain store has not developed extensively, and to which it seems to be none too well adapted. It is probable that less than 10 per cent of the retail hardware business is chain controlled. There seem to be various reasons why this business does not present an attractive opportunity to the chain store. Hardware stores typically handle a long line of merchandise, numbering between 2,000 and 10,000 items, many of which inevitably turn slowly. Their stock is of a very heterogeneous character and probably is not capable of being moved rapidly. Standardization of stock and service over wide areas is difficult because of the necessity faced by each store of adapting its business to the locality it serves. Capital requirements are somewhat high, although this is by no means an insuperable obstacle to chain development. The personal service factor is extremely important, as many customers of hardware stores look to the proprietor for information and advice in buying. Servicing of the product is also sometimes necessary. In the handling of certain hardware lines skillful floor salesmanship or even outside selling is a prerequisite of success. The "cash-and-carry" principle is often not adapted to this type of outlet, and the stock usually carried is of such a character as to make supervision and control from a central headquarters very difficult. Stores are relatively few in number—about 40,000 in the country as a whole—and widely scattered. Hence wholesale distribution economies probably cannot be realized. All in all we do not seem to have a strong case for the chain. It does not necessarily follow, however, that chains will not become an important factor in this trade. It is reported that a chain of several hundred stores operating in a number of states out of Minneapolis is meeting with success and is giving hardware jobbers serving the northwest very keen competition. There are several hundred hardware chains in existence, but most of them are of very small size. It should be noted, however, that certain items customarily sold by hardware stores are being sold in large volume by variety and drug chains.

As far as *geographical location* is concerned the chain type of retail organization has of course developed on the largest scale in the states east of the Mississippi and north of the Ohio. At the present time a very rapid growth is being experienced in the Pacific Coast states. And such organizations as the J. C. Penney Company are demonstrating that chain stores can be profitably operated in the South and West. Accurate data on chain volume by states unfortunately are not available. The subject may be dismissed by pointing out that generally large cities are the most fertile field for chains, with areas in which towns of 5,000 or more population are in close proximity to one another ranking next. The inference should not be drawn that the comparatively unpromising trades and areas will be immune from the chain influence. They have in countless cases already felt the effect of the chain and will probably feel it more as expansion of volume in the more verdant pastures becomes increasingly difficult.

Opposition to Chains. What measures have been taken to combat chains, and how successful have such measures been? Independent retailers, wholesalers, and certain types of manufacturers are the three parties who have shown the gravest concern over the so-called chain store menace. Either individually or in cooperation with one another they have resorted to countless devices for the purpose of self-preservation. Much ingenuity, and incidentally considerable naiveté, has been displayed in building up a case against the chain. The following excerpt from an address delivered before the American Retailers Association is fairly typical of the defense mechanism that many independent retailers and wholesalers have set up:

Chain stores serve to weaken a town because they draw money out, whereas the independent retailer spends his profits at home. The chain manager fails to participate in local civic and charitable enterprises, while the independent dealer contributes to these projects and handles the town's credit business and is otherwise a part of its existence. With a clear understanding of the situation once in their minds, no business men or laborers or farmers should spend one penny in the chain stores of their towns. The few cents that they will save a year do not warrant their patronage. Wholesalers and manufacturers should help the independent combat the chain store menace, for they are only protecting themselves. Chambers of commerce should issue pamphlets arousing public sentiment against the chain stores.

The argument is so absurd and futile as to be pathetic. Chamber of commerce pamphlets will not destroy the chain store. The "patronize home industry" appeal is of course attractive to many, but it is not the foundation upon which the trade structure of this country has been erected.

One also hears that chains do not employ local help, that they pay low wages, pay lower taxes than local merchants, are of little value to local bankers, tend to make us a nation of clerks, "limit the opportunity of American manhood," and centralize the business of the country in few hands. Space does not permit dealing with each of these points separately. Suffice it to point out that if the consuming public felt strongly that chain stores had an anti-social effect, chains could not prosper. Let it also be noted that mass merchandising is in a sense merely an extension of mass production to a new field—and the tremendous growth of the latter in the past half century, pro-

duced on a large scale exactly the same conditions which the chain store merely extends.

But the defense against the chain has taken the form of something more tangible than bad reasoning and futile gnashing of teeth. Among typical defense measures are the following:

1. Efforts to legislate or tax the chain out of existence. Laws passed in Pennsylvania, North Carolina, South Carolina, Georgia, Indiana, and Kentucky are cases in point. Several of these laws have already been declared unconstitutional by the courts.
2. The formation of operative groups of retailers or jobbers or both, for the purpose of securing either the advantages of chains or comparable efficiency in management.
3. The merging of jobbing concerns (*i.e.*, McKesson, Robbins) to secure the advantages of large-scale operation.
4. The adoption by manufacturers or jobbers of plans designed, through training or otherwise, to enhance the efficiency of independent retailers.
5. The opening of their own retail outlets by manufacturers.
6. Heavy advertising by manufacturers (and in a few cases by wholesalers) to establish a brand preference too strong for chains to ignore or overcome.
7. The adoption by manufacturers of price or other sales policies which do not favor the chains.
8. Efforts on the part of wholesalers to bring pressure upon manufacturers and force them not to sell chains.
9. Organized efforts on the part of independent retailers, often supported by jobbers, to exploit the service appeal, and convince the consumer that the economy of the chain store is really a false economy.

It is impossible to say with what success all these measures will eventually meet. One is reasonably safe in expressing the opinion that in the long run it will do no good to legislate against the chain (except as such legislation may be necessary to curb unfair competition), to engage in boycotting those who do business with the chains, or to organize for the purpose of exploiting a selling appeal which does not have widespread popularity. Whether cooperation among retailers, wholesalers or manufacturers will solve the problem is difficult to say. Cooperative groups have in many instances been successful; in numerous others unsuccessful. In the last analysis cooperation does not give the same advantages as can be obtained by an organization bound together by authority. In volume advertising, direct selling and similar measures manufacturers undoubtedly have powerful tools with which to combat the strength of the chain when circumstances are favorable.

In the long run the only successful method of meeting chain store competition will be to fight fire with fire. Unless competing agencies can find a way of rendering comparable services at comparable prices they cannot survive. Chain store competition can be met only by matching the chain store in efficiency of operation, or by so organizing as to secure the advantages of mass merchandising which now accrue to the chain. The miserable showing that has often been made by established agencies in combating the chain is in considerable part due to an unwillingness to face this fact squarely. The whole matter is well summarized by the following quotation from an editorial in the *Retail Ledger*:

The merchant who finds his own methods less efficient than those of his competitor will do better to study his competitor with a view towards adopting such of his efficiencies as he can, than by berating that competitor as a menace to American business.

This same counsel applies to manufacturers and wholesalers as well as to retail merchants.

Effect of the Chain Store on Distribution. Speaking in general terms, the growth of the chain has undoubtedly brought about a more compact, more highly integrated and better organized system of distribution than formerly prevailed. Because of its peculiar characteristics it has greatly sharpened competition and has tremendously stimulated the application of intelligence and resourcefulness to the solution of distribution problems.

It has affected the *retailer* in various ways. In countless cases it has resulted in the elimination of the small independent dealer. It has compelled the great majority of independent retailers, who would survive, to study their problems and evolve more efficient methods. It has in considerable measure been responsible for the formation of cooperative associations and syndicates whose main purpose has been to strengthen the independent's position in buying and selling. It has in all probability brought about a concentration of the retail trade in the hands of a relatively small number of stores. Whether it has caused a reduction in the total number of retail units is not known, but it has unquestionably reduced the percentage of the total retail volume in the hands of small independent merchants.

The position of the *wholesaler* has also been weakened by the chain. In numerous instances, particularly in the grocery, dry goods, and drug trades, wholesalers have been forced to go out of business. In many other cases they are finding it very difficult to maintain volume. The chain has also compelled in a number of instances the abandonment of small-scale, narrow-gauge methods, and has forced wholesalers to consolidate either with one another or with retail units in order to secure the advantages of integration and mass operation. Not only have actual mergers been brought about, but a great many cooperative experiments have been and are still being tried. For the first time in their business history wholesalers have been compelled to recognize fully the importance of efficient retail outlets to themselves, and to take such measures as will tend to secure such outlets. Wholesalers have also found it desirable to cultivate more intimate working relationships with manufacturers and to try to persuade them to adopt policies which will give them complete protection. In all probability the adoption of private brands by wholesalers is attributable in part to retail competition as well as to the competition of manufacturers' brands.

Finally, what effect has the chain store had upon the *manufacturer*? It has of course in some instances weakened the market position of the manufacturer and threatened his domination of the consumer. This explains the somewhat radical prediction of some that manufacturers' advertised brands are doomed. For many manufacturers the chain has created the question of which of two horses to ride—and how. Frequently, of course, the problem is one of trying to ride two horses simultaneously. The tendency in certain lines, notably groceries and drugs, for chains to develop private brands obvi-

ously threatens the dominance of manufacturers' brands. The tendency towards control of manufacturing by chains, which is observable in some lines, also creates a problem for the manufacturer. In the drug field chains are doing some of their own manufacturing of such products as rubber goods, writing paper, food products, candy, ice cream, hospital supplies and toilet preparations. Grocery chains often operate their own bakeries, roast their own coffee and produce their own canned and bottled goods, and meats. The mail order chains are producing their own paint and selling it under their own labels, and by so doing are creating for paint manufacturers a real problem. Such a trend may well cause some disturbance in the minds of large-scale producers at least. Looking further, the growth of chains has in innumerable instances compelled manufacturers to take an active interest in the wholesaling and retailing of their own products, and occasionally to engage in their own retail distribution. It has in a few cases been responsible in part for the formation of mergers or cooperative organizations designed to permit direct marketing and more effective control of distribution. And finally it has in a large number of instances forced manufacturers to face squarely the blunt question as to whether to cooperate with the chains or fight them.

What Is the Probable Future of the Chain? Prediction in the chain store field seems to border upon folly, yet to everyone in business who is affected by the chain it is of practical importance. Yet I am inclined to hazard the following guesses:

1. In lines in which the chain is already well developed it will continue to increase its volume rapidly for some years to come. Added volume will come primarily from hitherto unexploited geographical areas, from the adding of new lines and through growth and shifting of population.

2. In lines in which the chain type has not yet assumed an important position it will also make progress, although through a different type of organization than that which has characterized such lines as groceries. I would not be surprised to see chain growth in these industries progress at a moderate rate for many years to come.

3. Control of manufacturing and of brands by chains will progress rapidly in certain lines where circumstances are favorable, but I do not share the view that manufacturers' advertised brands will disappear.

4. Distribution generally will become much more highly integrated than it has been, the tendency being to develop wholesale and manufacturing facilities to match retail outlets rather than to attempt the construction of retail facilities to dispose of the chance output of wholesale and manufacturing units.

5. With the passing of the old generation a new crop of merchants will gradually appear, better equipped with modern merchandising and management ideas and technique, and capable of meeting the competition of large organizations successfully. Whether these merchants will be content to operate single stores or will develop their own chain organizations remains to be seen.

6. Cooperation and organized effort will become much more important and prevalent among individual retailers than has been true in the past.

7. The distribution machinery in general will be geared for economical operation and the strategy of merchandising, the slogan of which is now

"high quality at a high price" will be supplanted by the strategy of "high quality at the lowest possible price."

8. A number of chain organizations will, within a decade or two, control a sales volume in excess of one billion dollars each.

9. Distribution through manufacturer-controlled retail outlets will become more prevalent, but will not develop in certain trades.

10. Manufacturers and chains will come to recognize common objectives and will cooperate in distribution rather than combat one another. This trend is already in evidence.

11. The independently owned retail store will not disappear but will in many instances be a vastly different enterprise from its present-day counterpart.

CHAPTER XI

EXPORT MANAGEMENT

By E. B. FILSINGER, *Foreign Sales and Merchandising Counselor*

This chapter is addressed not so much to the executive who is already experienced in export work as to one who is starting in the field. This explanation is necessary lest those who are thoroughly versed in export trade practice find it elementary. Although intended principally for beginners, it has been planned with an eye to the development of a business, which though at first small, may eventually assume large proportions.

Accordingly, even those who direct a business of large magnitude may find herein suggestions for procedure which may be of value. As a matter of fact, it may be stated unequivocally that the principles of conducting overseas trade are precisely the same whether the volume be small or large. This is something that is often overlooked.

When a large manufacturer enters a new market, he must go through the same motions as must the smaller man. He has to be equally careful about his *relative* expenditures. From the proportionate or relative standpoint, a smaller manufacturer of the right kind of goods that are saleable abroad can perhaps make a larger net profit than can the huge corporation. He can, in exactly the same fashion and at no greater *relative* cost than the large concern, build up a satisfactory volume of business.

Making Haste Slowly. Far too many firms suddenly decide that they wish export business. Through ignorance they expect instantaneous results. This is a serious mistake. If useless expenditure, errors of judgment and misdirected effort are to be avoided, it is essential in building export sales to "make haste slowly." The failure to understand this has not only often resulted in heavy losses, but has so discouraged beginners in foreign trade that they have permanently lost all interest in exporting.

The beginner should realize at the outset that many of the firms who are doing the largest and most profitable overseas business today, use the utmost caution and conservatism in the initial stages of export trading. They thereby avoid not only disappointment but costly mistakes and wasteful effort.

Organization of the Export Department. To build a successful export business it is not necessary for the beginner, whether large or small, to create a huge organization with a correspondingly large overhead. It is wise to feel one's way. Expansion can take place as developments justify. However, one principle must be followed regardless of the size of the concern. It is this: One individual must be placed definitely in charge of the export depart-

ment. He must be held responsible for results. Success cannot be expected if the responsibility is divided. Many failures in attempting to build overseas trade may be traced to the failure to recognize the importance of this principle. If the head of the concern, the domestic sales manager, the advertising manager, the production chief, and the credit man, all attempt to dabble in the many problems that arise in connection with export, failure is almost inevitable.

Assuming that the individual chosen to manage the export department is of the right caliber, he should be placed on a parity with the domestic sales manager. He should report preferably to the titled officer to whom the domestic sales manager is answerable. In certain forward-looking concerns the president is interesting himself in both domestic and export sales. When that is not possible, one of the other high officers should do so. In the case of a small firm, the head thereof should require the export manager to maintain continuous contact with him. This is recommended because if the chief executive takes no interest in the developments, it is likely that the export manager may make a mystery of what is transpiring. The result will be that overseas business will come to be looked upon as merely a necessary evil, and that the solution of the problems that arise will rest wholly with the export manager. In a properly conceived plan for expansion overseas, the export executive occupies a seat at the council table. He is called into consultation whenever there is a discussion of policies, no matter what their nature. This is logical for the reason that many products, with slight changes, may be adapted to foreign demand. It is to be assumed that the right type of export manager will keep himself continuously informed regarding changes in buying habits, styles, methods of distribution, and advertising. In matters of production, if the views of the export department are obtained at the outset, later costly changes in method and packaging may be obviated. The export and domestic sides of the business can and should dovetail. The wise executive will maintain peace in his business family by avoiding the cause of friction between these two important ends of the business. It is accordingly highly desirable that this principle be borne in mind from the start.

The Ideal Export Manager. It is assumed that in deciding to build an overseas market the intent is serious. Permanent overseas sales cannot be found if export is merely a process of dumping when business is poor at home. Nor would it be possible to obtain the services of the right sort of individual to head the foreign division if that were the policy. The right type of export executive must like his work. He must have sympathy with foreigners and be able to get their point of view. He must not be a "know-it-all." He will take the trouble to inform himself thoroughly about everything likely to affect sales in foreign countries. He will be the type of individual who, knowing that his own reputation is at stake, will not go off half cocked. He will have the courage of his convictions and be willing to stand up and oppose a policy which in the light of his investigations he knows to be erroneous. He must not be afraid of detail. Export knowledge is a mosaic of innumerable facts gathered over a long period of years, in many places, and in all sorts of ways. Very often the right individual can be found in the domestic organization. If this is impossible, he should be sought outside.

Nor should the fact that a man speaks one or more foreign languages be held to fit him to undertake the duties of an export manager. In the selection of a foreign sales manager the language qualification ranks rather low.

The Duties and Responsibilities of an Export Department. In the case of larger concerns, who are doing a successful export business, it is frequently the custom to centralize in the export department, functions other than selling. These include shipping, credits, collections, financial arrangements, advertising, etc. However, it is rarely practicable in the case of a firm that is just beginning an export business, to adopt this principle, nor is it necessary that it should be done. It is of course assumed that the export manager will thoroughly inform himself about every detail in connection with packing, shipping, handling of documents, obtaining credit information, etc. Orders should be given by the chief executive that the mechanical carrying out of these details be in the hands of the respective departments that deal with them in the domestic end of the business. Supervision and final responsibility for their carrying out must, however, rest with the export manager. When the business (after development) has assumed proportions justifying their concentration in the export department, it is advisable that this be done. It makes for undivided responsibility and for greater efficiency. When the carrying out of instructions is left to various departments the likelihood of error is much greater. As concerns the granting of credit, it is a moot question as to whether this is a proper responsibility for the export department. In certain large organizations the export credit man is answerable to the head of the foreign division. Necessarily the volume of business done must be a large one to justify a separate credit department. The limits of space make it impossible to deal here with the many details connected with shipping, credits, financing, collections, etc. However, at the end of the chapter will be found reference to a list of books and publications in which a great deal of information about these subjects may be obtained. It cannot be too strongly urged that there be no penny-wise and pound-foolish policy about supplying the export department with the necessary tools with which to work. An intelligent conservative expenditure in this direction will pay good dividends. Mistakes are costly and can easily be avoided.

Sources of Information. The beginner in export has today available a fund of information undreamed of ten years ago. The most important source is the Bureau of Foreign and Domestic Commerce at Washington, D. C. There is scarcely a commodity or manufactured article about which it cannot quickly supply the necessary data as to the prospects for its sales in foreign markets. For the convenience of the American businessman district offices are maintained throughout the United States. It is highly desirable therefore that the district manager be approached by the prospective exporter. If the requisite information is not on hand it can usually be obtained in Washington. If not available there, arrangements can be made to acquire it through the foreign representatives of the Bureau, *viz.*, commercial attachés and trade commissioners who are scattered throughout the world. By cooperation with these officers and with American consuls, the department is able, in a very short time, to supply data, not only in regard to the saleability of goods but likewise to make definite suggestions for possible representatives with

whom correspondence may be undertaken. It cannot be too strongly urged upon beginners to consult the representatives of the Bureau of Foreign and Domestic Commerce before circularizing foreign representatives of the bureau and American consuls generally. In all likelihood, the information required is already on hand in Washington, consequently, much time and considerable money may be saved by obtaining the facts there. Furthermore, should it be necessary to send a questionnaire to the field representatives, this should likewise be done in cooperation with the bureau chiefs. Most of the letters sent to field representatives of the bureau and to American consuls are wholly inadequate in that they do not give sufficient information upon which the United States government officials abroad can act intelligently. Attention should also be drawn to the innumerable pamphlets and publications issued by the Bureau. These likewise contain important facts which throw light on the sales problem of the prospective exporter.

But there are also other sources of information, not only in regard to markets, but as to the best export practice. In many cities there are *export managers clubs*. The individual placed in charge of the export department should immediately make application for membership therein. The leading body of this sort is the Export Managers Club, Inc., of New York City. This club has in its files a vast amount of information on many phases of exporting. Upon request it will be supplied. If the desired facts are not on hand, the service committee will circularize the members and obtain the required data. From the members of these organizations, in analogous, but not in competitive lines, may also be obtained data and the names of possible foreign representatives.

In almost any library may be found the proceedings of the National Foreign Trade Council. The conventions of this body have been held for the past sixteen years and the published reports, of the speeches made, contain a great deal of practical information. Other organizations that may be consulted are the Chamber of Commerce of the United States at Washington, the American Manufacturers' Export Association, New York, the National Association of Manufacturers, New York, etc. Besides these sources, may be mentioned the publications of the Overseas Trade Department of Great Britain and those of the Canadian government. Books, many of which have been recently published, relating to individual countries and which are likewise available in almost any library, also supply many side lights and suggest possibilities for the sale of manufactured products. In brief, with a little effort the beginner in export can quickly determine whether his product is saleable in foreign countries. However, it is self apparent that it devolves upon one individual to coordinate not only advance study but definite sales efforts, if success is to be achieved.

Proper Filing of Market Data. It will be found in practice, that once the study of foreign markets has commenced, a great deal of information will begin to pour in. Under ordinary circumstances this would be placed in the general correspondence file. Nothing could be more shortsighted. From the outset, all the information bearing on an individual country should be filed separately. This will make it possible to consult it frequently and freely.

Furthermore, as new facts become available they will take the place of obsolete information. In this fashion a country file will always be up to date. This method, simple as it is, will, over a term of years, result in the collection of an invaluable fund of information. Obviously, if placed in a general file, a huge waste of money and effort will result.

Departmental Organization of Foreign Division. The export department should be built to meet future needs. This can best be accomplished by territorial divisions. For a concern that has real possibilities in overseas markets, the need for experienced men to send out as travelers will soon become evident. By organization of the department in territorial divisions, the man destined, say, for Latin America, the Far East, or Europe, can be automatically trained. As the business in one or the other of these territories assumes sufficiently large propositions to justify the sending of a man, he will have become available. That is, if, in the meantime, he has been assigned by the export manager to familiarize himself thoroughly with the country to which he is going, with the correspondence from abroad and all details of the sales made in his division. As part of his duties, he not only oversees the filling of the orders, but attends to the correspondence with local representatives, and customers. He does the necessary follow-up work and writes to prospective customers. The training of the young men, who will eventually become travelers, is a highly important step in the development of any overseas business. By this method it will be possible not only to familiarize them with the intricacies of the business but likewise to make a study of their conduct, character, ability, etc.

Precautions Regarding Instructions. Another precaution that it is desirable to take, is the following: From the outset, special instructions from foreign customers, regarding labeling, packing, marking, declarations, shipping, etc., should be carefully filed. This information must be kept in such shape that in the absence of any particular individual there will be no lapse from instructions. Mistakes, because of failure to follow directions are costly and fines are often imposed. Another good precaution to take is to place, in the upper right-hand drawer of each clerk's desk, an instruction sheet relating not only to specific customers, but to every duty that he must perform. This should be kept up to date by periodical checking. Standardization of practice minimizes errors both of omission and commission.

Alternative Methods of Exporting. There is no cut and dried formula for developing an overseas business. Only in a few highly specialized lines can hard and fast rules be laid down. The beginner has various channels of distribution available to him. These, roughly speaking, are as follows:

- a. Export commission houses (New York, San Francisco, New Orleans).
- b. Foreign local representatives, *i.e.*, sales direct to importers or dealers.
- c. Foreign customer representatives or distributors (exclusive territorial rights).
- d. Direct by mail solicitation.
- e. Very large foreign buying organizations such as chains, and cooperatives.
- f. Traveling salesmen.
- g. Combination export managers (even if these are used, one individual in the firm should still be charged with responsibility for export sales).

In practice, these methods (with the possible exception of the traveling salesmen) may be utilized by a merchant or manufacturer regardless of the size of his business. Frequently, large houses have recourse to at least the first five. It has been found by experience that the best and most lasting results are usually obtained by having local representatives in the principal markets. The trend, generally, during the past five years has undoubtedly been in that direction. It makes for more intimate contact with the ultimate distributor and consumer. As to export houses, it is possible, indeed under certain conditions desirable, to utilize their facilities also. They are taken advantage of by many exporters under the following conditions:

- a. In certain markets (principally smaller ones) where they have no local representatives.
- b. For buyers in places difficult of access.
- c. In markets where the export houses sell to certain firms whom the American manufacturer does not wish to solicit direct.
- d. Where the export houses buy outright under their own brands, etc.

Sales made through these channels obviously do not conflict with established representation agreements. In cases where orders are received through export houses for shipment to territories where an American firm is represented, a commission is usually reserved for the local representative.

Market Research and Analysis. It is an amazing fact that many business houses seem perfectly willing to spend money in an experiment with foreign trade, who consider it a useless waste of time to make studies and analyses before going ahead. They demand plans, specifications, details from their architects or engineers, but not from their export managers. Far too many American firms are still willing to appropriate large sums for technical and scientific research, although unwilling to make similar appropriations for market or sales research. They do so to insure improved methods of operation, better quality, lower costs, etc. It is more important than ever that the principles of scientific market analysis and sales research be applied to overseas trade. Some of the sources available have been previously indicated. Many more are at the command of exporters. When it is remembered that there are over one hundred countries, the impossibility of listing the individual sources of information in this chapter will become apparent. Suffice it to say, the principles of market analysis in foreign countries can be applied with the same perfection as in the United States. In some cases naturally, it is not as easy to apply the yardsticks commonly employed in the domestic market, but nevertheless, they can often be used. The beginner in exporting owes it to himself to make market studies. He need not do it on a vast scale. However, he should certainly make a very careful analysis of his prospects in a few of the more promising markets, that is, where the early indications point to possibilities. Upon the outcome of these studies will depend his method of approach, viz., the choice of method for entering the market.

Trial or Test Campaigns. Once having satisfied himself that there is a good prospect for the sale of his product in one or a few countries, he should take the next step. It is at this stage that many of the disastrous mistakes

in exporting occur. The would-be exporter suddenly imbued with a desire to export is not satisfied to go slowly. He wishes to accomplish everything over night. This is very shortsighted. No matter how encouraging the prospects, he should proceed with caution. It is preferable that he try out his proposition in one or two countries. If at all possible, they should be neighboring ones. If the neighboring fields do not offer the best possibilities then he is justified in entering more distant ones. However, in principle, he should concentrate on one or two countries. This will enable him to thoroughly prove his proposition and make his mistakes on a small scale. By following this course he will be able to avoid needless errors, prove his plans, and acquire more speed in the third, fourth and fifth countries that he enters. The most successful and largest American firms, even in their domestic territories, rarely launch national campaigns. They use trial or test campaigns in restricted areas. This sound principle should invariably be applied by the beginner in foreign selling. By such a test he will be able to learn what changes in his product may be necessary: the people to whom he must advertise, the appeals which he must use, the expenditure that will be required, the best method of marketing, etc. Especially will he be able to inform himself regarding one of the most important factors in overseas selling, that is, his price policies. He will be able to determine whether or not his system of discounts is appropriate, whether to adopt a method of price fixing and price maintenance, how to avoid price cutting and if he is justified in advertising the retail price. Incidentally, he will likewise be able to give some thought to the method of setting quotas. This is an end which he will eventually wish to achieve. Every fact that his initial studies in one or two countries reveal, can be utilized to advantage in later campaigns.

The Export Sales Manual. One of the most important benefits of a trial or test campaign in one or two countries has yet to be mentioned. It is the acquisition of information on which to base a sales manual or instruction book. It is to be assumed that the enterprising beginner in export has already prepared for his domestic sales staff a sales manual which embodies the chief facts about his product. However, in practice it will be found that in foreign countries it will be necessary to amplify or change the manual to make it fit into local conditions. His initial efforts in his experimental fields will show him what is lacking and needs to be added. As a result, when he enters his third, fourth and succeeding territories, he will be in a position so to present his proposition that time can be saved. The export sales manual need not be an elaborate or fancy book. It should contain the indispensable information in regard to the product, suggestions for meeting objections, etc. Frequently and certainly, at the outset, while in the period of development, such sales manuals need be only mimeographed. After a year or two the final edition will be so well worked out that the foreign representative to whom it is sent will be able to offer the product as intelligently as though he had been trained in the home office.

Sales Budgets and Quotas. Obviously, it is impossible for the beginner to make sales budgets and to set quotas. However, it is amazing with what rapidity this can be done once a start in selling has been made. The beginner's goal should be to set up sales budgets and quotas as rapidly as possible.

It should be no more difficult for the smaller manufacturer to do this than for the large one, the principle involved being precisely the same. Quotas are based on towns, cities and customers; then there should be additional quotas for lines of goods or single items therein. The quota is a mark at which to shoot. After the first year or two it is possible to achieve a high percentage of efficiency in fixing quotas. Naturally, local representatives should be consulted when quotas are in process of being assigned. So, too, should the traveling salesman. The reasons why certain figures are set should be explained to the local representatives and their own comments taken into consideration. The periodical checking of accomplishments, preferably on a month to month basis, and an analysis of results obtained in relation to the facts in hand makes for constantly increasing efficiency. Eventually it will lead to a forecasting of sales, cash receipts, stock on hand, etc. It cannot too strongly be urged on the beginner in export that he attempt at the earliest possible moment, to introduce a system of sales budgeting and quotas.

Expense and Profit Budgets. Profits are the goal of every business. These are often achieved in two ways: (1) greater sales, (2) avoidance of waste and losses. At the outset, it is possible for the beginner to determine how much money he is willing to spend for the various details in his initial campaign, including salary of an export manager, and trials or tests. It cannot be too strongly urged that an account be kept of the expenses incurred in all sales efforts. They should not be on the basis of a department as a whole, but by countries and by individual items of expense. The reasons for this will become apparent after a little experience. A sharp eye must be kept on the benefits derived from the various expenditures. It is on the relative value of these expenditures that future plans depend. In far too many cases, manufacturers who do business, say in a dozen countries, are making a profit on 25 per cent of their business and dissipating it on 75 per cent thereof. It should be sought scientifically to determine what sort of sales effort yields the best results. It should also be the aim to decide which type of sales promotion work, missionary salesmen's efforts and so on pay the best dividends. By carefully watching the expenses from the beginning, thereby knowing the facts, the manufacturer can not only insure himself a larger net return but he can make his money go much farther. As fast as new territories are entered, simultaneously with sales budgets and quotas, should be set up expense and profit budgets. Expenses should be broken down item by item. If this system is followed the manufacturer can save himself many disagreeable surprises.

Sales of Branded Goods. The manufacturer who markets his product under a trade mark has a distinct advantage. A trade mark is sales insurance. Not infrequently, especially in the initial stages, the sales resistance to trade marked goods is considerable. Often it is greater than on unbranded ones. Notwithstanding this fact, some of the greatest successes achieved in export selling have been on branded articles. It may require greater effort to sell trade marked merchandise, but on the other hand, once the demand has been created, the manufacturer, not the importer, is in control of the situation. Identification of merchandise permits its advertising and special sales promotion work. Without identity such sales efforts would go for naught.

Accordingly, from the very outset the beginner should plan to extend sales assistance to the dealer. In marketing many products no cooperation can be expected from the dealer unless such assistance is given. Even though there may be an insistent demand from the foreign merchant for unbranded goods, the American exporter should insist upon introducing his own brand. Should the American capitulate to the foreigner he will learn to his regret but all too late, that he has enabled the latter to build up his own business and has laid himself open to the possibility of substitution. Branded goods once introduced and supported regularly with advertising likewise enable the manufacturer to insure himself larger profits as well as permanency of trade.

The Importance of Advertising. Naturally, certain products, notably in production and machinery lines, require little or no advertising to the consumer. However, in the case of consumer goods, the beginner will quickly learn that unless he supports the foreign dealer with advertising, his business may be of very restricted volume or completely unsuccessful. Fortunately, there is a large fund of concrete advertising information and experience available to the beginner. There are advertising agencies which specialize in export advertising. Usually they work through local advertising agencies in the various foreign countries. In addition, certain of the larger American advertising agencies have in recent years extended their activities abroad. They maintain local offices in important centers and their American offices are equipped not only to give the fullest information regarding media, rates, circulation, etc., but also to outline campaigns, suggest appeals and advise fully regarding every phase of a well rounded sales promotion campaign. Export advertising should be planned long ahead. Six to nine months is not too far in advance of a campaign. This permits the submission of the details to the foreign representative for his suggestions and criticisms. It is highly desirable that this plan be followed in order to secure the fullest cooperation. In principle, the American manufacturer should himself control the advertising. Only in rare instances has it proved wise to allow the foreign representative to prepare the advertisements and to place the campaign in the papers. Arrangements should be made to "play up" the advertising to the local merchants. Precisely the same principles covering the coordination of advertising, sales promotion and selling apply in overseas markets as at home. In planning the introduction of consumer goods, arrangements should be made at the outset to support selling efforts with appropriate publicity.

Protection of the Trade Mark. The beginner who sells his products under a trade mark should take immediate steps to protect his brand in the markets where he plans to do business. Through trade mark attorneys the brand should be properly registered. If this is not done, he may suddenly discover that some enterprising foreigner, viz., a trade-mark "pirate" has registered the brand in his own name, either for the purpose of obtaining a cash payment from the unwary American business man or to secure for himself the representation of the concern. There are innumerable instances of this kind on record. Not only have excellent American products been completely excluded from certain foreign countries but in many cases, American concerns, who failed to take the simple precaution of registration, have had to pay through the nose for their oversight.

While on the subject of trade marks, the advantage of an easily pronounced name should be pointed out. Even though a brand may be well known in the United States, if it is not pronounceable or unsuited for one reason or another in a foreign field, it may be advisable at the outset to adopt a new name and trade mark that is appropriate. This likewise may save money in the long run. On the subject of trade mark registrations, valuable suggestions and information may be obtained from the Bureau of Foreign and Domestic Commerce.

Use of Sales Promotion Material. It is a truism that sales promotion material, display signs, booklets, etc., can generally be used abroad as successfully and effectively as at home. Obviously they must be in the language of the country. Much money can be saved if a simple precaution is taken. Before making shipments of sales promotion material to foreign representatives, single pieces should be sent to them for their approval. This is advisable because the duty on printed matter is often very high. Not infrequently display material can be obtained more cheaply locally than if shipped from the United States; when the latter system is followed, not only freight but tariff must be taken into account. Booklets, catalogues, in fact every sort of printed matter in foreign languages, if translated in the United States, before being printed, should likewise be submitted to the foreign representative. This precaution will save embarrassment resulting from incorrect use of words or phrases. Since color and illustrations in certain foreign countries have a special significance (notably in China and in the Near and Far East) it is highly important before contracting for large expenditures to consult the foreign representative. In passing, the importance of correct translation generally must be emphasized. This applies to all correspondence, but especially to initial letters soliciting answers or relating to agency arrangements. Reliable representatives are often scared off by badly translated letters.

Special Development Fund for Export Trade. Once the beginner has satisfied himself that there is prospect for the sale of his merchandise abroad, he should definitely determine how much money he is willing to spend on the development of his market or markets. This applies even to the preliminary or experimental efforts. If the results are sufficiently encouraging, he should definitely set aside a certain fund for further expansion. His investigations may indicate that not only no profits, but even a loss, may result from his first or second year's work. In order that he may be constantly aware of what his work is costing, he should set up a special development fund. This may be broken down in various ways, including sampling, sales promotion material, advertising, and commissions. It should be further broken down by countries. In reality, it is an expense budget. As bills are received they can be charged against the appropriate items. By following this method the situation will not get out of hand and he will be able to exercise a more exact control. It is highly advisable to follow this method even though the expenditures are written off, that is, charged to profit and loss as fast as made. Inasmuch as foreign business frequently cannot be made immediately self supporting, many concerns establish a special development fund. They look upon it as an investment to insure future profits and amortize it over a period of

from five to ten years. The method that is followed depends entirely upon the attitude of the manufacturer. However, it cannot too strongly be insisted upon that the most careful record of expenditures be kept. If this is done, it will permit the spending of larger sums in the more promising fields and withdrawal from those markets where neither the immediate results nor future prospects seem to justify the investment.

The Development of Export Salesmen. The greatest successes in overseas selling have been achieved by those firms who send their own representatives to canvass foreign markets. The advantages of this method are so obvious that no discussion is necessary. Precisely the same principles apply in this regard as in the domestic field. To a greatly increased degree, it will be necessary for American manufacturers, particularly those who produce highly technical apparatus, to send abroad technicians who can act both as demonstrators and salesmen. They are in effect sales engineers. However, even in the case of ordinary merchandise, *viz.*, consumer goods, the presence of a salesman on the ground frequently means the difference between success and failure. One of the causes of greatest waste in overseas sales effort has been the sending of the wrong type of salesman. It is becoming increasingly evident to a number of American manufacturers that the best results can only be insured by sending into the field men not only carefully trained, and thoroughly familiar with the product they are selling, but whose reliability and sales ability has been proved by a course of training and observation for a period of from six months to several years. The beginner, as soon as he has convinced himself that he has encouraging prospects, should prepare for his future sales efforts by undertaking the training of his sales staff. There is no cut and dried formula for developing export salesmen. Sometimes the right individual is found in the domestic department. Occasionally he must be employed from the outside. Some may be partially trained—others fully trained. Young men may be taken from colleges or universities, especially those which give courses in business training. Even though the best methods of selection are followed some failures are bound to result. In principle, it should be sought to develop their initiative by assigning them to tasks of one kind or another in the export department. Occasionally it is found advisable to let them demonstrate their selling ability in the domestic field. They may also canvass export houses, wait on visiting merchants, etc. As to training in general, the same methods may be followed for export as in the home market. The most important consideration is that the prospective traveler familiarize himself thoroughly with every phase of the product. In this respect the export sales manual will be helpful. Obviously, if the salesman is eventually to be sent to a Latin American country, he should learn Spanish. He should likewise, by a course of reading, familiarize himself with the countries to which he is to be assigned. The greatest stress should be laid on developing his salesmanship qualities. No salesman should be sent abroad unless he knows his business thoroughly and possesses such qualities that the chief executive is willing to invite him to his club.

Information Given the Salesman. No matter how carefully the salesman has been trained, nor how competent he may be, before leaving for his territory, he should be supplied with the necessary information to make his

trip a success. Nothing should be left to chance. As far as possible the routine of equipping export salesmen should be standardized. This will greatly simplify the sending of salesmen later to other fields. Among the indispensable items are the following:

- a. Full details of the market analysis made at the outset. This to include data of every sort bearing on sales prospects, regardless of origin.
- b. Record of sales made from the beginning and divided by departments, lines of goods, and kinds.
- c. Record of purchases of individual customers, also from the beginning.
- d. Information regarding customers' methods of payment, comments of the credit department, and complaints.
- e. Complete lists of prospective customers, for investigation.
- f. Quota sheets by departments, lines, kinds, towns, and customers.
- g. Suggestions and hints for canvassing the territory, methods to be used and so on. Campaigns. Sales promotion material. Details regarding past and projected advertising.
- h. Copies of representation agreement.
- i. Copies of correspondence with other possible representatives.
- j. Itemized expense sheet showing expenditures by items up to date of departure.
- k. Budgets of expense by items.
- l. Sales manual or information book.

In a word, the salesman should not be expected to trust to his memory for any important detail. As an additional precaution, a questionnaire should be prepared covering those phases of the market or marketing methods about which the export manager is either uninformed or concerning which he wishes additional data. This will not only save the salesman's time, but will insure that no important item is overlooked.

Determining the Relative Importance of Quality, Style, and Price. The beginner should realize that in foreign markets, identically the same conditions prevail in the matter of quality and price as in the United States. There are lines of goods demanded in which price is an important factor. In others, style is dominant and in still others, quality and finish. The situation is analogous to that in the United States where there is both a price and quality demand. In the average American community there are some stores that sell only on the basis of quality, others in which the keynote is low price. In the great American department stores, goods may be sold on the upper floors on the basis of style and quality; in the basement departments, price is all important. The beginner should determine for himself at the outset into which category his lines fit. In reality there is nothing incompatible in trying to sell goods both on a quality and price basis. It is important, however, to determine where the most promising prospects and profits lie and to evaluate one's facilities for taking proper care thereof.

Developing Goods Special for Foreign Markets. In overseas merchandising elasticity of mind is a highly desirable quality. Occasionally no changes whatever are necessary other than perhaps in the matter of label and packing. On the other hand, experience may prove that it is desirable to make certain slight changes. Properly planned merchandise, saleable in foreign countries

may be produced under mass production methods and interfere in no way with the domestic output. Occasionally, changes required to insure saleability abroad may even benefit the product in the domestic market. It is for that reason that the export manager should participate in all conferences relating to policy. His suggestions frequently are of the greatest value.

Selling on Credit. One of the most important factors in the development of an overseas trade is the extension of adequate credit terms. The beginner should realize the day has passed when a letter of credit can be demanded with the expectation that it will be opened. A study of foreign conditions will quickly show why foreign merchants require credit. Here are some of the reasons: The length of time goods are in transit; in the customs house while being cleared; en route to the interior; the heavy cash outlays for duty and freight charges; the time that the foreign dealer must grant to his own clients—sometimes four to six months; and always the factor of the unexpected. It is no longer difficult to obtain reliable credit information regarding foreign buyers. Credit is being successfully extended by English, German, French, Italian, Spanish, and other exporters. The merchants of these countries freely grant sixty days to six months on open account, sometimes even longer. They have been doing so for hundreds of years. Following are only a few of the sources from which credit reports may be obtained:

1. Personal contact (salesmen or local representatives).
2. Other firms dealing with the customer (American and Foreign).
3. American and local banking institutions.
4. The Foreign Credit Interchange Bureau of the Nation Association of Credit Men.
5. American Mercantile Credit Agencies (Dun's and Bradstreet's).
6. Local credit agencies.
7. The Commercial Intelligence Division of the Bureau of Foreign and Domestic Commerce at Washington.
8. United States consuls.
9. United States commercial attachés and trade commissioners.
10. Miscellaneous sources.

With ordinary precautions it is possible to grant credit as safely in foreign countries as in the United States. The combined experience of a great many manufacturers engaged in overseas business indicates that the total loss is less than one-half of 1 per cent. In many cases it is nil. The beginner should realize that if he expects to build up an export trade he must grant reasonable credits and that he can do so with no greater risk than in the home market.

Organizing the Export Executive's Work. It may appear from the foregoing that the work of an export executive with so many details to look after becomes unwieldy. As a matter of fact, with proper organization, this is not so. The export executive can be supplied periodically, daily, weekly, or monthly, as the case may be, with comparative statistical records that enable him to see at a glance the trend or tendency of his business. Such reports should be as simple as possible. They should reveal weakness and strength. He is thus enabled to apply almost instantly, remedies that if applied later

may prove unavailing. Nor is it incompatible with his daily work to make his studies of future markets. Sales research must be extended over a considerable period. With the help of an intelligent secretary he can direct even the largest and most complicated export division. The beginner should never forget that it is best to make haste slowly.

Coordination of Export and Domestic Activities. It is highly important that from the outset the export department be considered an integral part of the business. It must not be accorded an inferior position. Innumerable successes achieved by leading American firms prove not only that by proper coordination it is possible to develop a satisfactory export trade, but that it can materially aid the domestic output. The advantage of an additional 10 to 20 per cent of business from overseas as it affects profit possibilities is so obvious that no comment is necessary. The all important thing is that there be a thoroughly sympathetic attitude towards the development of an export business, from the president to porter. The profit possibilities of a successful overseas demand are so large that no effort is too great to realize them.

Bibliography

Limits of space make impractical the inclusion of a bibliography. Readers are referred to the following: "Foreign Commerce Handbook," issued by the Foreign Commerce Department of the Chamber of Commerce of the United States, Washington, D. C.; "Selected Bibliography of Foreign Trade," issued by the National Foreign Trade Council, India House, Hanover Square, New York City. An invaluable reference book, containing a mine of practical information, is the "Exporters' Encyclopaedia," published by Messrs. Thomas Ashwell & Co., 20 Vesey Street, New York City.

CHAPTER I

THE FINANCIAL EXECUTIVE'S PART IN MANAGEMENT

By D. W. HARRIS, *Vice President and General Manager, Arkansas Natural Gas Corporation*

The development of business, bringing to life large combinations of capital with far-reaching activities, has brought heavy responsibilities to the shoulders of the financial executive. Earlier methods of business organization permitted lesser responsibilities and presented more simple problems. A concern which could operate with one or two bank accounts and whose requirements for credit were moderate, because of a narrow scope of operations, would often permit a morning jaunt on a country road for the fortunate executive of former days or send him daily to his seat in the grandstand, when the ball team returned for the home series. No such happy routine exists nowadays for the financial executive, who steals his golf on a holiday afternoon, or leaves a pew vacant on Sunday morning, while a martyred family awaits his return for a belated lunch. Credits, banking relations, long term financing, and budget revisions have taken their toll of his time.

Importance of Broad Viewpoint. One of the important problems resulting from the present-day organization of business arises from the creation of separate responsibilities for the various executives who are carrying on the management of the business. A concern whose activities embrace such a variety of operations as the production of crude oil, the refining of petroleum, the marketing of its products, the transportation and distribution to customers, and the manufacture of natural gasoline through absorption plants of necessity requires the supervision of many executives who possess expert qualifications in their particular lines of endeavor. The job of the financial executive demands that he fit in his viewpoints with the operating executive in each division of his organization, thus compelling him to view every problem presented, not only from the standpoint of his ability to finance the project, but also from the perspective of the operator, whose consideration is primarily that of facilitating more efficient operations and production. To analyze the increase or reduction in expense, to evaluate the probable increase in earnings and to weigh the operating advantages incident to the completion of the project against the cost of capital to finance it, the determination of his ability to provide such capital and the methods with which he will provide it are some of the problems of the financial executive. Increase in efficiency of operations must be encouraged, cash and credit

must be conserved, and his conclusion and concurrence must find the happy medium, which does not always exist, between the two viewpoints that focus on the proposal. To accede on the one hand, without proper regard for the factors which are his own particular problems, may bring embarrassment and failure; and to veto, on the other hand, without seeming to lend a willing hand and without the ability and endeavor to point out strong reasons, with logic, diplomacy, and tact, may destroy the spirit of cooperation desirable at all times, kill the initiative of the operator, still his ingenuity, and impair the possibility of efficient coordination of the numerous departments of the business.

It is apparent that in order to equip himself satisfactorily to cope with the demands which will constantly come to him from the operating heads, the financial man must have a fairly comprehensive understanding of operations requiring continuous inquiry on his part and a broad classification of information to be ready at his disposal, which is only possible from careful study and intimate acquaintance with the operating units of the property. Such acquaintance may be augmented by a friendly association and social contact with other executives wherever opportunity presents, with the incidental advantage of establishing at the same time the human relationship which tends greatly to promote a satisfactory meeting of minds in the conference room, when divergence of opinions on business matters arise.

Some Duties of the Financial Executive. It is obvious that the more simple of the financial executive's functions would consist of receiving and disbursing the company's funds, with the attendant details of recording all transactions, as well as accepting the responsibility for passing on credits extended in the course of current business, together with the collection of all accounts accruing to the company. All of these functions present their own peculiar problems, and the methods used in obtaining results are of more or less common practice, so that a discussion of these items of responsibility in this paper, in detail, is hardly necessary. Suffice it to say that the item of credits has a vital relation to the company's business and its own financial standing and for that reason should receive careful attention and supervision from the financial officer of the company.

The fundamental duty of a financial executive demands a constant realization of his responsibilities to the owners of the enterprise. A proper appreciation of this primary responsibility will insist that invested capital shall bring a fair return, that additional capital shall be provided for necessary expansions to produce the same result. In order successfully to administer these obligations, additional functions are created. A satisfactory credit position must be maintained for the company, a wide acquaintance must be established with banks, investment houses, and other financial agencies and a thorough understanding should be had of the various methods of financing, giving proper regard to the fact that temporary banking credit is available only for current transactions and that capital expenditures must ultimately be provided from more permanent issues of stocks or bonds. To the financial executive whose organization is receiving the benefits of customer or employee ownership there is added the duty of assisting in the promotion and furtherance of goodwill among the company's employees, customers and friends lead-

ing to the creation of an ever-increasing number of satisfied partners. This is accomplished through the distribution of understandable and reliable information together with the maintenance of a proper relationship with these people as security holders. In this case the financial executive is also responsible for the initiation and maintenance of proper security sales policies whether distribution is effected through employee campaigns, through full-time sales force carried by the company or through investment bankers.

Economic Conditions and Trends. A constant survey of economic conditions and trends should be maintained in an effort to anticipate periods of industrial or business depression so that capital may be provided for future contemplated expansions under advantageous conditions at reasonable rates. Fortunately there are a number of business services today which employ large staffs for assembling and digesting data from over the entire civilized world. This data is collated and boiled down to a few pages in order that the busy financial executive may have at hand concrete facts in his judgment of the present and future economic situation.

The Financial Statement. The financial statement is the basis for all credit negotiations. For this reason, the executive must scrutinize each important transaction, keeping in mind the probable effect it will have upon the financial statement. Capitalization and bonded debt must be maintained in proper proportion to fixed investment. Additions to plant and permanent investments should not be permitted unless the annual return will safely provide the fixed charges for interest and dividends on the new capital invested. A proper ratio of current assets to current liabilities should be maintained as an evidence of ample working capital and to safeguard against sudden and unexpected adverse fluctuations in the business. As a further safeguard against quick, unfavorable developments in the industry, ample bank lines should be available as a cash resource to meet such situations when urgent need arises. Inasmuch as banking credits are granted only where speedy liquidation is apparently possible, the quick asset position of the company is important as is also the ability to meet fixed charges of interest and dividends from current earnings. Banking credit cannot be commandeered at will. It results most readily from a satisfactory experience in previous transactions, which includes the maintenance of accounts profitable to the banker and record of prompt attention to maturing obligations, as well as being founded upon a periodic credit analysis made possible by the frank presentation of statements, which will permit a complete and thorough understanding of the company's operations, business and financial position. The financial executive is therefore interested and must insist that the accounting procedure of his company be administered in a manner which will enable him readily to present a statement of the business which his banker will understand and make it possible to answer satisfactorily and completely the questions which the banker will undoubtedly ask.

The Financial Executive and the Budget. Manifestly, few human minds could intelligently administer these responsibilities and properly exercise these functions in a large and complex business without depending to a considerable degree on the associates, who are in charge of the various units of the business. To supplement such a deficiency in human ability and to

provide the necessary procedure for information and contact the annual budget of operations in all its phases has come into being. This budget cannot be a mere catalogue of intended expenditures, but should include a careful analysis and estimate of all the elements in detail of the operating program for the year. It should be so designed that it will train all of the managers of the various activities of the business in forecasting future requirements of their respective units and supply a test of their judgment by a comparison of actual results with the predictions that have been made by them, appraising their ability to foresee the opportunities which exist in any situation and their capacity to realize their expectations. In its final form, when presented to the financial executive, the budget should represent the coordinated estimates of all the managers of the business, consolidated into a well-balanced outline of the future activities of the entire company. It should be built upon the basic fundamentals of volume and price and should provide for periodic revisions made necessary by variations in these two factors, which will, of necessity, occur in every industry.

In no business with which I am familiar, is this more necessary than in the case of a company engaged in the production, manufacture and marketing of crude oil and its products, an industry in which the fluctuations of price are both rapid and frequent and the volume of production is always uncertain. For example, you will recall the situation in the oil industry in 1921. During that year the price of crude oil in the Mid-Continent field declined from a peak of \$3.50 per barrel in the previous December, to \$1.00 per barrel in the following June. Again, in 1923 six major pools were discovered, producing in excess of 100,000 barrels per day in each pool. Not only did this sudden increase in volume of production depress the price of the commodity, but the increased drilling activities forced the oil companies who held acreage in the areas of discovery to develop such acreage during the period of declining prices and at a time when the supply of crude oil was greatly in excess of the demand. The financial executive for the oil company was therefore not only confronted with the problem of readjusting the financial situation of his company, because of the reduction in income, but was also compelled to supply additional financing for the development of the leases owned by his company in the areas of discovery.

No executive of any business is more intimately concerned with the budget, its preparation, the accuracy of its forecast and the restrictions of its appropriations, than the financial officer of the company. To him it is a blue print in dollars of the year's operation; it enables him to plan with foresight, with judgment and with accuracy, fortifying his own judgment with the combined judgments of his associates; it enables him to finance properly and economically; it enables him to project the financial statement of the company into the future and to visualize what the financial position of the company will be when the budgeted program is completed.

If the operating management imposes upon the financial executive the responsibility for providing capital needed in the business and passes judgment upon his ability to meet such demands as they arise, an obligation, in turn, rests upon the operating management to provide its financial officer with information, in detail, as to the extent of the capital requirements that will be

needed, at a time sufficiently in advance of its use to permit of the production of such capital in the manner most suitable to the items for which the additional capital is to be expended. Thus there is established a relationship between the operating and financial executives, leading to a concurrence of judgment in matters of importance to the company's welfare.

Conclusion. From this study of the financial executive's part in management and his relation to other executives, are we not to conclude that his part in management is an important one? However, the entire management should represent the combined judgment of all in charge, whatever the individual functions may be, a judgment to be attained only by the patient cooperation of everyone responsible for the destinies of the enterprise. Credit is sensitive, personal contacts are valuable, and unstinted cooperation carrying with it the combined advantages of each individual personality goes far in making the job easy for those who are called upon to do it. It is not the purpose of this discussion to emphasize the importance of the responsibilities which rest upon the financial executive without expressing an appreciation of his obligations to his associates. It is the aim, rather, to lay stress upon the factors with which the financial officer is compelled to deal and to solicit for all executives a better understanding of the interdependence between the different departments of the business.

Enjoying cordial relations with his associates, a strong credit position for his company, a complete and accurate budget, a list of friendly banks, and a ready market for his company's securities, our burdened financial executive may not be required to desert his church pew on Sunday morning, to the delight of his family and, of course, to his own supreme satisfaction.

ties realized more clearly that the investor is buying future earnings as well as safety for his principal. They realized the vast difference between the earning power of assets and liquidation value. As the result the financial investigation was supplemented by the industrial survey which determined the facts necessary to discover and evaluate the economic reason for existence of the business, presented a diagnosis of the financial, sales, and manufacturing management of the business, discovered potential earning powers and brought to light other facts bearing upon the probable future earning power of the business.

Such facts as those presented by the financial investigation and analysis and the industrial survey also became of increasing value to the officers of the company enabling them to better serve their stockholders through more effective administrative management.

While the investment bankers and those who serve them professionally were developing the financial investigation, the financial analysis and the industrial survey, the institutional bankers and credit men were developing a similar technique based on the analysis of financial statements by means of ratios.

The Ratio Method of Financial Analysis. Briefly the ratio method of analysis consists of setting up certain ratios between balance sheet items and between balance sheet and profit and loss statement items in such a way that the relation of one to the other is evident, that trends can be determined and comparison made with identical ratios existing in similar businesses. These are usually supplemented by operating percentages determined by dividing each item on the profit and loss statement by total net sales. This latter is very often popularly referred to as "the distribution of the sales dollar." The ratio of current assets to current liabilities, usually known as the liquidity or bankers ratio is an example of the first type, the ratio of sales to fixed assets or vitality of fixed assets ratio is an example of the second, and the percentage of sales expense to net sales is an example of the third variety.

This whole movement has been the result of the application of scientific management, which is management based upon the collection and analysis of facts, to financial management much as it had been previously applied to manufacturing management and to sales management. While there were certain leaders of the movement the results attained could not have been secured without the collective action of corporation officers, bankers, credit men, accountants, engineers and others who realized the need for more exact and comprehensive methods of financial management and administrative control.

The recognized pioneers in the field of analysis of financial statements by the ratio method are James H. Bliss whose work on the subject was published in 1923, and Alexander Wall, secretary-treasurer of the Robert Morris Associates, a national organization of bank credit executives.

The ratios used by Mr. Wall are clearly set forth in the book "Ratio Analysis of Financial Statements" from which the following discussion of the subject has been excerpted.¹ These ratios are as follows:

¹ Excerpted by permission of authors and publisher from the book by Alexander Wall and Raymond W. Dunine, Chaps. VII, VIII, and IX, Harper & Brothers, 1928.

1. Current ratio.
2. Worth to debt.
3. Worth to fixed assets.
4. Merchandise to receivables.
5. Sales to receivables.
6. Sales to merchandise.
7. Sales to fixed assets.
8. Sales to net worth.

Current Ratio. This ratio is secured by dividing the total of the current assets by the total of the current liabilities. The result indicates the dollars of current assets as offset for the dollars of current debt. The current assets will normally turn into cash or its equivalent in the near future, thereby putting the owner in possession of funds with which to pay debts. The current liabilities will mature in the near future, at which time the creditors will expect payment. From the liquidation of the current assets the current liabilities will be paid. The higher, therefore, the current ratio runs, the freer the current assets are from debt claim by creditors, and the more likely creditors are to receive prompt and complete payment upon demand.

The Robert Morris Associates have found that it is simpler to express ratios in terms of percentages rather than as proportions; for example, instead of speaking of the current ratio as "two to one," greater accuracy and simplicity can be attained by expressing it as 200 per cent.

In reading the current ratio, or any ratio, the analyst must remember that the ratio for any single statement is only a momentary pause in the movement for that company. The same identical current ratio figure for two separate companies may not represent the same credit condition at all. The value of the use of the current ratio lies in its record and direction of movement not in its one-time point of rest. The analyst must base his decisions not, therefore, on any one statement but on a study of the record of the company for at least three and if possible five years in order that the direction of the movement may be measured, as well as the single position.

The so-called "*acid test*" is often used to supplement the current ratio. It is computed by dividing the total of cash and trade receivables by the total current liabilities. To meet the test satisfactorily the total of cash and trade receivables must equal the total current debt. Cash is, of course, immediately available for use in debt reduction. Receivables are only one step removed from cash and are subject to bad-debt shrinkage only. Cash and receivables are, therefore, almost exactly opposite in character to debts which are maturing in the near future. The acid test is a drastic one. While it is not always easy to meet, it has the quality of conservatism. The analyst in applying this test must use discretion as in some lines the character of the industry may prevent the test from functioning fairly.

Another ratio often used as a corollary to the current ratio is that of *working capital to inventory*. This ratio determines the sufficiency of the current ratio. Working capital is the excess of current assets over current liabilities. Inventory consists of raw material, goods in process, and finished goods. The ratio of working capital to inventory measures the amount of working capital tied up in inventory. If a company has a 200 per cent current ratio,

but a large percentage tied up in inventory, this company, as a rule is speculating in merchandise. This, of course, does not apply to chain stores or others doing a cash business. Any ratio involving the inventory item needs careful examination. Inventory is the item most often used to window dress a statement. Subjecting it, therefore, to as many tests as possible may assist in uncovering window dressing operations.

In the past too much reliance has been placed on the current ratio as a test of financial soundness. It is undoubtedly an important strength measurement in that it establishes the relation between debts maturing in the near future and the assets from which these debts are to be paid. As soon as it had become generally known that analysts accepted a current ratio of two to one as a standard indication of a sound financial condition, companies through window dressing operations set out to show this proportion on their annual statements. It has been found, therefore, that other ratios are necessary to discover the true financial condition of a company, and, that the current ratio alone is not a sufficient test of financial soundness.

Worth to Debt. This ratio is derived by dividing the true net worth by the total debt, including both current and funded debt. The net worth of a company is the sum total of the capital stocks both common and preferred, surplus and undivided profits. In short, net worth represents the difference between real assets and the obligations. It is the economic capital provided by the owners.

The ratio of worth to debt expresses the proportion existing between the capital owned by a company and the capital loaned to it by creditors. When a company must use the capital of some one else at all times to support its volume of business, it has taken the first step toward the so-called "top-heavy" condition. When the relation between the net worth and debt is below what is normal in the industry, the company's condition may be criticized as top-heavy with debt. The ratio of worth to debt ought to be watched as closely as the current ratio. It is probably as important a ratio as the current ratio. The higher the ratio of worth to debt the easier the debt pressure and the further removed the company is from being top-heavy with debt.

Worth to Fixed Assets. The ratio which results from dividing the true net worth by the amount of fixed assets expresses the proportion between the owned capital and the money not currently invested. Any net worth may be reasonably accompanied by a certain investment in fixed assets, but when the net worth is too small in proportion to the amount invested in fixed assets, the company is "overinvested in plant." If the ratio is abnormally low for that type of industry, too much of the company's capital may be invested in a fixed form. The ratio measures the reasonableness of plant investments. To supplement the worth-to-fixed-assets ratio, the ratio of *net worth and funded debt to fixed assets* is sometimes used. The fixed assets are taken gross. The latter ratio is a test of plant expansion and indicates how much of the stockholders' and bondholders' money is left after supplying the fixed assets.

Merchandise to Receivables. To derive this ratio the inventory total is divided by the total of trade accounts and notes receivable. The resulting ratio expresses the relationship between inventory, a cost item, and receiva-

bles, a selling-price item, which together usually form the predominating factor in the total of current assets.

Either an upward or downward movement of the current ratio may be largely or even entirely due to some conversion or movement of the ratio between merchandise and receivables. The analyst should watch the variations in the ratio of merchandise to receivables in order to ascertain whether the change in the current ratio is basic, or merely due to a change in the form of asset.

The fluctuations of this ratio, then, in a measure check the fluctuations of the current ratio. This ratio can also be used to indicate the preponderance of either merchandise or receivables in the current assets which makes a considerable analytical difference in estimating probable losses or profits due to inventory fluctuations in different phases of the business cycle.

Sales to Receivables. To obtain this ratio the net annual sales are divided by the total of trade accounts and bills receivable. The resulting ratio expresses the relationship between the total annual business and the outstanding receivables which are the uncollected sales for the period.

Receivables are the credit extensions of a company. A company which sells on a cash basis has no receivables; its sales furnish immediately the funds with which debts may be paid. So long as the sediment of receivables is not greater than usual in an industry, any single company is but meeting trade conditions. When the ratio of sales to receivables falls below the usual, then the customers of that particular company are slower in making payments than is customary throughout the industry. This of course indicates that an added expense of financing is necessary, inasmuch as the company must have extra capital with which to carry the slow paying accounts.

The larger the sales are in comparison with the receivables the more nearly the subject has approached to a complete collection for the period and the greater the probable liquidity of the receivables. Conversely, the lower this ratio the greater the probability of the presence of poor collection methods and stale receivables. An unusually high relationship, however, is to be questioned and carefully investigated as it may indicate that the company has resorted to the expedient of selling or hypothecating its receivables to a finance company and has not reported the contingent liability. When both the ratio of sales to receivables and the ratio of merchandise to receivables are badly distorted compared with common or average industry proportions it is particularly important to make a careful check in order to detect possible hypothecation of receivables.

Sales to Merchandise. This ratio is derived by dividing the net annual sales by the total merchandise inventory. The resulting ratio expresses the proportion between sales and merchandise which, while not a definite physical turnover indicator, is a comparable measure of turnover from year to year. The ratio is useful in discovering excessive inventory and possible speculative tendencies of the management. In other words, this ratio is helpful in determining whether the management is accumulating inventory beyond its present needs with the hope of profiting by probable price rises.

Merchandising capacity can be measured, within reasonable bounds, by the sales developed per unit of inventory. The higher the relationship of

sales to inventory, the greater is this merchandising capacity and the more probable the freshness, salability, and liquidating value of that inventory.

Sales to Fixed Assets. To obtain this ratio the amount of the annual sales is divided by the amount of the fixed assets. The result indicates the sale productivity of fixed assets expressed by the relation of sales to the money invested in fabricating, trading, or non-liquid assets.

Every dollar that is invested in fixed assets can be justified only if that investment results in a sales volume that will be reasonably productive. Unless sales result the investment is unsound and illogical. Mere volume of production is not always an indication of managerial ability; if the unit of production falls per unit invested the increased volume has been achieved with increased inefficiency. The relation of sales to fixed assets is a measure of the production results of capital and of the economic soundness of such an investment.

When the net worth to fixed asset ratio is falling, accompanied by a decline in the ratio of sales to fixed assets, liquid capital is being transformed into fixed capital at a more rapid rate than new capital is being added to the net worth. This investment is, accordingly, relatively less productive. When such a condition is accompanied by a declining net worth to debt ratio, the "vicious circle" is complete even though both net worth and sales may be increasing.

Sales to Net Worth. This ratio is derived by dividing the net annual sales by the true net worth. The result reflects the sales activity of the invested capital. When this ratio is increasing at a rapid rate from year to year there is danger that the company is "overtrading" that is, attempting to finance a volume of business too great in comparison to its own capital. Any slowing-up of sales or collections might make emergency borrowing imperative. If the ratio of sales to net worth is much above a reasonable proportion, there is always this danger of overtrading. On the other hand, if this ratio is far below usual, the capital of the enterprise is stagnant. As the ratio falls, the business may gradually lose its market and end in extinction.

Supplementary Ratios. While Mr. Wall and Mr. Duning recommend the above seven ratios as important additional tests to the generally accepted current ratio, they also suggest the following ratios as useful at times to explain or further emphasize conclusions which have been reached:

1. Net profit to sales.
2. Net profit to net worth.
3. Cash and receivables to current debt.
4. Net worth and funded debt to fixed assets.
5. Funded debt to fixed assets.
6. Working capital to inventory.
7. Raw material and finished goods to goods in process.
8. Working capital to total assets.

The two ratios, *cash and receivables to current debt* and *working capital to inventory*, are explained in the preceding section on the current ratio, and the ratio of *net worth and funded debt to fixed assets* in the section on the *net worth to fixed assets* ratio.

The ratio of *net profits to sales* is useful as a test of the profitable operation of a business. It naturally varies from industry to industry, dependent upon the usual turnover of receivables, merchandise, and net worth. This ratio varies, naturally, too, with the swings of the business cycle.

The ratio of *net profit to net worth* is a measure of the return upon the capital invested in the business by the stockholders. Mr. Wall and Mr. Duning would define net profits as the amount of profits which remain in the business after dividends, taxes and depreciation have been deducted.

The ratio of *funded debt to fixed assets* can be used as a supplementary test to the fixed asset ratios. As a measure of the extent to which the fixed assets are mortgaged this ratio determines the future possible borrowing power through mortgage bonds. In case of a low current ratio, the ratio of funded debt to fixed assets is useful in determining the probable extent to which fixed assets might be used for possible future borrowing through mortgage bonds.

The ratio of *raw material and finished goods to goods in process* applies only to a manufacturing concern. Raw material and finished goods are salable; in case of the liquidation of a company, goods in process must either be junked or additional expense must be incurred to put these goods into a finished state. This ratio, therefore, relates to the question of balanced inventory, and is of only secondary importance.

The ratio of *working capital to total assets* measures the liquidity of the working capital, and indicates how much of the total assets are free for the current operations of the business.

Bases for Ratio Analysis. No set figure can be given as the universal proper proportion for any of the ratios which have been enumerated. The usual or expected proportion varies from industry to industry. Processes by which the customary proportion for an industry may be discovered are discussed in detail in Chapter XI, Bases for Ratio Analysis.¹

Index of Credit Strength. The eight practical ratios recommended by these authors, as previously discussed, are not all of equal importance. To arrive at a real index of credit strength they must be weighted according to their relative importance in forming a credit opinion of any one company. A method of arriving at an index of credit strength with suggested weightings for seven of these ratios is to be found in Chapter X, under the title of Indexing Credit Strength.² The merchandise to receivables ratio is not used in the index because it changes, as a measure of underlying strength, at different times in the business cycle.

Importance of Analysis of Working Capital. It might be well also to draw attention to the fact that in a test analysis of unsuccessful industrial companies including a group of statements for twenty-nine enterprises representing seventeen different kinds of industry, the Bureau of Business Research of the University of Illinois³ found that approaching financial difficulties are

¹ *Ibid.*, pp. 166-179.

² *Ibid.*, pp. 152-165.

³ See University of Illinois *Bulletin* 31, "A Test Analysis of Unsuccessful Industrial Companies," July, 1930.

clearly indicated by the working capital position of an enterprise. The ratio of working capital to total assets, as indicated by this study, is perhaps even more useful for analyzing the soundness of an enterprise than the current ratio. According to this study, the analysis of working capital must be considered at least equally as important as the current ratio in an analysis of the current position.

Conclusion. While the technique of preparing a financial analysis from adequate financial statements is comparatively simple, once standard ratios and operating percentages have been determined upon, a considerable knowledge of accounting is necessary to avoid mistakes in entering the figures against the ratios and misinterpretations in drawing conclusions. Furthermore a complete financial analysis requires considerable knowledge of business and of the particular business in question.

The financial analysis should always be the first step in preparing the industrial survey which should then discuss such matters as the history and organization of the company, its products, competitors, market, sales methods, manufacturing methods and the like, all of which presuppose wide experience in finance, sales and manufacture as well as business judgment. The general method presupposes this knowledge and an analytical mind capable of securing and presenting the essential facts in logical order. The facts will differ in each case so that the ability to weigh evidence and draw correct conclusions is necessary.

FINANCIAL BUDGETING TECHNIQUE

BY CHESTER E. WEGER, *Manager, Budget Department, Henry L. Doherty & Company*

This discussion is to be confined, as far as may be practical, to a discussion of only one aspect of budgeting, namely, financial budgeting technique, using the methods and procedure of the Doherty organization as the specific examples.

Each of the individual operating companies under Doherty supervision, and there are more than a hundred of them, has its own management and operating personnel and each one functions as an independent unit in its own locality. All construction work is carried on under the responsibility of the local management and all bills are paid locally. In New York there is the central office where the executive staff is located. This means that there is in New York a central treasury in charge of the chief financial officer of the organization whose duty it is to pass upon the financial policies handed up to him by the local companies for his concurrence and to recommend the major financial policies for the organization and supervise the carrying out of those policies which are adopted.

To further clarify our minds as to the budget relationship between the New York office and the local properties, let me quote from an executive communication to all local property managers:

It is understood that the central office executive committee deals with every problem involving the expenditure of cash, strictly as a budget problem and views it with reference to its effect on the whole situation. The full

responsibility rests with every company manager and he must have such knowledge of his own budget situation as will enable him to control the individual factors affecting his budget so that the overall conditions agreed upon will at all times be carried out.

The wisest preparation of budgets is understood to be a first and fundamental duty and the carrying out of a budget already agreed upon is the first and primary test of the efficiency of the manager of every property.

This quotation fairly well defines the responsibility of the local managers to the executive committee in New York.

These New York executives are on the other hand responsible to many thousands of security holders for the safety of the principal which they have invested and also for the income on that principal to which the investor may be fairly entitled.

It is really impossible to consider financial budgeting as a topic by itself, apart from construction or operating budgets. Generally speaking, the opportunity for financing is founded upon considerations of capital investments and net earnings from such investments. By the very nature of this fact, the chief financial officer cannot alone be made responsible for the finances of the company, because capital invested and the earnings therefrom largely predetermine the opportunities for financing.

What Constitutes a Financial Budget? Financial budgeting in its broadest sense is particularly a management consideration. The treasurer's efforts alone can influence only certain items in the financial budget, so that the amount of the company's resources which he can turn into cash is circumscribed by external limitations of credit which are imposed by considerations of earning power and investment. In view of what has just been said, it seems clear that in considering the technique of financial budgeting, we ought not to overlook the important bearing which both the plant and investment budget and the earnings budget have on the financial budget.

In the Doherty organization, the financial budget is based upon estimated changes in the balance sheet. All of the various operations which enter into the business of any company requiring cash or its equivalent are thus covered by the financial budget. The projected changes in the balance sheet accounts expressed as additions to cash or deductions from cash comprise the financial budget. We commonly refer to this budget as the cash budget or more exactly as the consolidated budget, because it reflects all the activities of the business combined or consolidated into one estimate.

Admittedly this form of cash budget is not so simple as the more familiar form of cash budget which deals strictly with cash receipts and cash disbursements. It would be impractical for the New York office to attempt to keep informed about one hundred different local situations if their respective financial budgets were compiled in terms of expected cash receipts and cash disbursements. To be sure, such cash budgets can be made to reflect very accurately the cash production or cash requirement of a company and such statements do have a useful function in the treasurer's daily check on the cash till. But those who look after the finances of the company are interested in more than this. What information does cash receipts and disbursements afford the local management or the New York executives about business results or the effect of business policies? Collections from customers this

month bear no tangible relation to this month's reported net earnings. Cash disbursed for operating accounts bears no relation to the month's reported operating expenses. Similarly hardly an item on the conventional receipts and disbursements statement is of any value in the determination of significant business facts. From day to day, receipts and disbursements statements can be used to provide the treasurer with daily information about the state of the cash balance, but the individual in charge of the finances of the company will need to review the past and plan for the future, using balance sheets and earnings statements as a basis for his conclusions.

A Banker's Confidence in the Financial Budget. It has come to be recognized that through the financial budget we have a means of approach to the banker which is calculated to increase the confidence which he may have in management. Confidence is the basis of most credit arrangements so that if the budget system operates in such fashion as will permit one easily to interpret the estimated future results in terms which the bankers can understand, the budget system will undoubtedly have a favorable influence on banking relationships. When one reveals to the banker future plans, and takes him with complete frankness into one's confidence, there is bound to spring up a mutual understanding and respect which is certain to be of assistance. The balance sheet method of budgeting has outstanding advantages in this connection.

At any rate, balance sheets and finances are so intimately connected that our subject today instead of being financial budgeting technique might equally well be called balance sheet budgeting technique. It certainly seems to me that if it is proper to consider past results from the standpoint of earnings statements and balance sheets, it is of equal importance that we look into the future with the same kind of consideration.

Very early in the budget history of the Doherty organization, we adopted the balance sheet method of budgeting. Perhaps this method was forced upon us as being the only method which effectively made each elusive dollar, that passed through the cash box, tell from whence it came and why; also whither it was bound and when. It is surprising the number of places to which the dollars disappear in the average business and a goodly portion of business failures are directly traceable to a lack of appreciation of the host of semi-unproductive uses for capital that were overlooked when the financial budget was first compiled. Advance payments for insurance, stationery, etc., advance payments on equipment or stores purchases, special cash deposits, estimates exceeded on expenditures for additions and improvements to plant account, increased inventories over the estimate, failures to allow sufficient lag for collection of customers' accounts, the extension of longer credit terms to customers than allowed for in the original budget—these are only a few of the ways in which dollars may be unexpectedly hidden away, and their cumulative loss to the cash till usually causes no little concern, and often, financial embarrassment.

The balance sheet method of budgeting assures that consideration will be given to all such items as mentioned, to the end that the financial budget will be a more comprehensive statement of the expected future cash conditions of the company.

Let me explain by means of charts more precisely how the balance sheet budget is arranged. Figure 1 for example, shows at the top a summarized statement of the estimated earnings which, of course, is supported in much

FIG. 1.—EARNINGS BUDGET

	Advance estimate, calendar year	Actual previous year
Gross revenue.....	230,000	200,000
Operating expenses.....	172,000	150,000
Net earnings.	58,000	50,000
Interest expense.....	8,000	6,000
Net profits to dividends.	50,000	44,000

FINANCIAL BUDGET

	Advance estimate, calendar year A	Balance beginning of year B
Net profits to dividends.....	50,000	147,000
Dividends.....	<i>20,000</i>	
Replacement reserve.....	8,000	8,000
Prepaid expenses.....	<i>1,000</i>	<i>5,000</i>
Interest accrued.....	3,000	4,000
Taxes accrued.....	2,000	7,000
Capital securities.....		350,000
Expenditures for plant and investment	<i>25,000</i>	<i>400,000</i>
Credits to plant and investment.....	13,000	
Stores and supplies.....	<i>10,000</i>	<i>50,000</i>
Customers' accounts received.....	<i>15,000</i>	<i>100,000</i>
Bank loans.....	<i>5,000</i>	25,000
Accounts payable.....	<i>5,000</i>	35,000
Cash.....	<i>11,000</i>	21,000

NOTE.—In Figs. 1 and 2 "red" figures mentioned in the text are shown in italics.

detail in accordance with the full classification of operating and expense accounts. This statement begins with gross revenue and concludes with the item of net profits applicable to dividends. It should be noted here that

the item of operating expenses includes many items which are not current cash transactions. For example, the expenses include the monthly accrual charges for replacement and, also, monthly charges for taxes, neither of which represent cash dispersed in any particular month. Since these items of expense are book accruals, some adjustment will necessarily follow later to bring the cash picture into line. The item of interest expense, likewise, is a book accrual without reference to the payment date.

The lower section of Fig. 1 shows in column A the budgeted changes in the balance sheet accounts. This is the cash estimate or consolidated budget previously referred to. Additions to cash representing credits to these accounts are shown as black figures, while deductions from cash representing debits to these accounts are shown in red figures. If the estimated debits to an account exceed the credits then the net change shown on the budget will appear as a red figure. The algebraic sum of the changes in all other balance sheet accounts when expressed in terms of their effect on cash, gives the change in the cash account itself.

Concerning the \$8,000 addition to cash estimated for replacement reserve, it may be well to observe that this amount is a net figure between a \$21,000 accrual which is an assumed concurrent charge to operating expenses and a \$13,000 debit which is written out of plant and investment and offset on the line credits to plant and investment. Likewise the item of \$3,000 for interest accrued represents the difference between the \$8,000 of interest expense charges and \$11,000 estimated cash payment for interest during the year.

In column B are shown the probable balances in all the balance sheet accounts at the beginning of the estimated period. This is for convenience and assists materially in understanding the significance of the budgeted figure. Credit balances are shown as black figures while debit balances are shown as red figures. This color scheme makes it possible to add algebraically the advance estimate to the balance at the beginning of the period and conclude at a glance what the balance in the account is estimated to be at the end of the budget period twelve months hence. For example, stores and supplies will increase from \$50,000 to \$60,000 at the end of the budget period while bank loans are being reduced \$5,000 which will make their total only \$20,000. Cash on hand at the beginning of the period is shown as \$21,000 and it is estimated that this amount will be reduced by \$11,000 so that only \$10,000 will be in the bank at the end of the ensuing twelve months.

Method of Handling Construction Program. The construction budget as submitted by the operating companies for concurrence includes only those construction expenditures that are considered necessary or unavoidable to the satisfactory operation of the local company. All that class of construction items which might be called urgent or desirable is submitted in requisition form and totaled for financial estimate purposes but not included in the authorized budget. This procedure has been found to permit more time and attention to be given to the engineering and economic phases of a large and important portion of the construction program. This method of handling the construction program is of importance from the standpoint of the financial budget. This is true for the reason that it permits the major portion of the construction program to be authorized from time to time throughout the

year after there has been an opportunity to give full consideration to keeping the new investment at the lowest point consistent with satisfactory operating conditions with a maximum earnings return. Thus there is a tendency to keep the return on all newly invested capital at the highest level which should result in constantly improving the company's earning power and its credit standing. Also this procedure reduces the amount of outstanding commitments for construction and thus might conceivably avoid the necessity of withdrawing authorizations for construction in order to conserve cash lost through an unexpected decline in estimated earnings. The financial man soon finds a very decided reluctance for cutting operating expenses in a period of depression to offset a serious loss in revenue. Conservation of cash in such cases may be brought about through a contraction of the construction program. It is much safer and less costly and also less disastrous to morale to defer authorization on new construction work than it is to withdraw an authorization previously granted and on which some expenditure may already have been made. Another advantage of the minimum construction budget is that it permits an intelligent selective process to be used on the urgent and desirable class of construction expenditure, making it possible to pick out those items which promise the best earnings return. This, again, has the tendency to increase the earnings on the invested capital, which above all, the financial man is interested to have accomplished.

The submission of the budget by the local operating companies is scheduled early in the month of December. The budgets are reviewed thoroughly by the New York executive staff and are recommended to the New York executive committee for their concurrence. If the budget receives the favorable consideration of the executive committee, it is adopted as final and used for comparison purposes throughout the following year.

With the adoption of the final budget the first step of budget procedure is completed. The second step, but not least important, is to follow up carefully the progress of actual results in relation to the accepted budget. In our organization the financial comparisons are submitted by the local properties once a month. A comparison is made for the one month just passed and also for the period to date, the period to date comparison being simply an accumulation of all the monthly comparisons. The actual figures are obtained by the simple subtraction of the latest balance sheet from the last previous one. The comparison statements are made in the accounting department.

Figure 2 shows the general form of the financial budget comparison for the period to date. The actual results are shown in column C with the original estimate for the same period in column B. The differences between the actual and estimate appear in column D. The items listed are exactly the same as those shown for the financial budget in Fig. 1. Here again use is made of black and red figures in the difference columns to denote increases and decreases to cash over the original estimate. Many people have little sympathy for the use of this color scheme in showing additions of cash and deductions from cash. However, it has distinct advantages, the first being that red figures assist in picking out at a glance the items which need attention and the second is that the number of columns required is very materially reduced.

The third logical step in financial budget procedure is the revising of estimates. Figure 2 shows that the comparison for the period to date carries with it also the revised estimate for the remainder of the period. The estimates are ordinarily revised once each month at the time the comparisons are prepared. However, provision is made for submitting supplemental advices at any time if important fundamental changes in the outlook warrant their special consideration.

FIG. 2.—FINANCIAL BUDGET COMPARISON AND REVISED ESTIMATE FOR REMAINDER OF PERIOD

41,000	Accounts payable.....	8,000	6,000	2,000	1,000	<i>13,000</i>	<i>14,000</i>
24,000	Cash.....	<i>5,000</i>	3,000	8,000	<i>6,000</i>	<i>6,000</i>	<i>12,000</i>

NOTE.—"Red" figures are shown in italics.

The original estimate stands unchanged and the revision is accomplished by adding anticipated differences from the estimate. Thus column G is the sum of columns E and F. This method of preparing revised estimates is used because of the great saving of time which results in handling difference figures only on items that need to be revised rather than total estimate figures for all items in the budget. It would be quite a task to prepare a completely new estimate for the remainder of the period and it is much less work to handle differences from the estimate on the lesser number of items which require revision.

When the monthly budget comparisons with revisions for the remainder of the period are received in New York, they come to the attention of the budget department. Here the statements are carefully analyzed, compared

with the advices previously submitted and all important new factors reviewed in the light of the explanations which have been presented. A condensed summary is then prepared for the information of the treasurer, setting forth the important new factors which have come about to change the budgeted situation in any respect since the last advice, transmitting to the treasurer the explanations as supplied by the company on important differences and giving that officer the effect of the new factors on the New York cash account.

The New York budget department summarizes all the advices which have been received from the local companies every fifteen days and otherwise revises and brings up to date the budget for the New York office. In transferring funds to and from the central treasury in New York and the local properties, the budget comparison and revised estimate is used as the basis for determining when funds are to be available and the amount to be transferred.

PRICE FLUCTUATIONS IN RELATION TO BUDGETING

By J. B. DEACON, *Hoffman Beverage Company; formerly Member Board of Directors, Tidewater Oil Company*

Profit is the objective of business enterprise. The price margin between commodities or services bought and those sold determines the margin of profit. Hence price fluctuations are of vital concern to management. That management which is well equipped accurately to forecast price fluctuations of the commodities it buys and sells, and to act appropriately with reference thereto, is well fortified against losses and failure.

The growth in size and complexity of business enterprises necessitates systematic planning and control. Systems of financial and operating control of industrial establishments increasingly involve budgetary measures. Among those who deal with budgets it is axiomatic that the success of a budget system depends upon the ease with which forecasts may be revised to reflect changes in policies, programs, performance and prices. Price fluctuations are probably among the most frequent causes of budget revisions.

Probably an oil company's viewpoint of this matter is a good one to examine for the reason that price changes are frequent and often extreme in the petroleum industry. Furthermore, in this industry raw material costs, relative to labor and other costs, are exceedingly high. From this it follows that ability to gauge price trends is a part of the essence of sound management. No matter how competent the management of an oil company may be in other respects, if there be lack of ability to maintain an inventory position nicely adjusted to price trends, financial disaster will result.

The following charts confirm the assertion that price fluctuations in the petroleum industry are frequent and wide.

Figure 1 shows the trend of crude oil prices (posted quotations at well) for representative grades for the period January, 1925, to February, 1929.

Figure 2 shows the trend of gasoline tank wagon prices for the principal marketing centers of the Northeastern states for the same period.

Figure 3 shows the price trend of refined products in New York Harbor, also for the same period.

The price variation of crude and products generally reflected in the following three charts is emphasized in Table 1 (page 352), which shows (a) the number of price changes from 1925 to 1929, (b) the price range, and (c) per cent variation between low and high prices.

FIG. 1.—Trend of crude oil prices—posted price at well.

Figure 4 compares price movements in the petroleum industry with those in certain other representative industries, and with the general commodity price level. The chart is based on figures compiled by the U. S. Bureau of Labor Statistics, representing wholesale commodity prices. For the period covered by chart (January, 1925, to February, 1929) the following spread occurred between the low and high index numbers.

	Low	High	Spread
All commodities.....	93.7	104.8	11.1
Lumber.....	87.8	106.7	18.9
Bituminous coal.....	91.4	116.8	25.4
Iron and steel.....	93.5	107.3	13.8
Petroleum products.....	65.6	106.6	41.0

FIG. 2.—Trend of tank wagon prices—gasoline.

FIG. 3.—Trend of refined product prices—New York Harbor.

From this point we shall attempt to develop the subject as a case study of the means by which an oil company with a system of budgetary control deals with price changes. The presentation will be most useful if we exhibit

FIG. 4.—Wholesale commodity price movement—U. S. Bureau of Labor statistics (1926—100 per cent).

that part of the oil company's budget system which is directly affected by price fluctuations, and actually work through the budget certain assumed price changes.

In observing the forms which are shown in the following pages you will please bear in mind that the figures shown are not the actual figures of any existing company. While the figures are fictitious, nevertheless they have been prepared with reference to giving as true a reflection of price fluctuations and seasonal factors as though actual figures had been used.

Let us now give mental birth to this oil company which with high originality we shall christen the "X Oil Company." The X Oil Company refines crude oil and markets the products. Its other operations are carried on through three subsidiaries, the A Producing Company, the B Pipe Line Company and the C Crude Oil Purchasing Company. The A Producing Company handles all producing activities—that is, all operations concerned with leasing and developing oil lands and actually getting the oil out of the ground. The B Pipe Line Company carries that part of the A Producing Company's crude, which is available to its lines, to the X Company's refineries. The C Crude Oil Purchasing Company buys a part of the A Producing Company's production and such additional crude as the X Oil Company's refineries require which cannot be procured directly from the A Producing Company.

TABLE 1.—PRICE VALUATIONS, CRUDE OIL AND REFINED PRODUCTS, JAN. 1, 1925, TO FEBRUARY, 1929

New York.....	25	15.0	22.0	47
Philadelphia.....	30	12.0	21.0	75

It is assumed that during 1929 the X Oil Company will market 1,000,000,-000 gallons of gasoline of which 800,000,000 gallons will be domestic dealer sales and 200,000,000 gallons bulk sales. In order to produce this volume of gasoline it will be necessary for this company's refineries to run 48,000,000 barrels of crude.

It is further assumed that the company produces from its own wells enough crude for its refinery requirements, but that only one-half of this production is actually available for transportation to the company's refineries through its own pipe line, and that the balance of the production is sold to other users of crude. In order, then, that the refinery crude requirements may be met, it will be necessary to purchase the other 50 per cent of its requirements, and so we assume that 24,000,000 barrels of crude will be purchased and transported to the refineries by the pipe line, along with the 50 per cent of the company's own production which is available.

This oil company's system of budgetary control is composed of financial and operating forecasts. The financial forecasts consist of:

1. Net income.
2. Cash receipts and disbursements.
3. Capital expenditures.

The budgets which are affected by price changes are net income and cash receipts and disbursements.

Table 2 is the consolidated 1929 net income forecast for the X Oil Company and its subsidiaries. It is dated Apr. 30. The first four columns embody the income figures of the four operating units of the X Oil Company group previously described. Column e combines the separate company figures into a consolidated total, which is the present view of 1929 net income. The next column f reflects an earlier view. From column f we conclude that this forecast of Apr. 30 represents a revision of some earlier forecast. That is a correct conclusion as will develop later. The last column g embodies 1928 actual figures.

The first three lines deal with the first quarter, Jan. 1 to Mar. 31, in terms of a comparison of the actual net income for the first quarter of 1929 with the estimate for that period and with the actual for 1928. We then have estimates of net income for each of the following three months—April, May and June. That is followed by an estimate for the balance of the year. The next line 8 represents the present view for the year, that is, the combination of lines 2 and 4 to 7. The following lines provide for the deductions of federal income taxes and preferred and common dividends, leading to net income to surplus and earnings per common share figures.

Underlying this master forecast of net income, of course, are the detailed financial and operating forecasts of the parent company and each subsidiary company.

This Apr. 30 forecast of 1929 net income is the latest of a series of forecasts, the first of which was set up in November, 1928. In November the management of each company of the X group formulates operating programs for the ensuing year, which are cast in the form of financial estimates, by quarters, of net income, cash and capital requirements. Before the first of the year

they are reviewed, revised if necessary, and ratified by the president in conference with his executive associates. Beginning with January, the budgets are revised monthly so that actual performance figures may be substituted for estimates, and so that effect may be given to any changes in prices or operating plans during the balance of the year. Revisions also take place at such other times as marked price or operating changes occur.

TABLE 2.—X OIL COMPANY AND SUBSIDIARIES. FORECAST OF 1929 NET INCOME, APR. 30, 1929

16 Earnings per common share.....					\$ 1.98	\$ 2.06	\$ 2.50

NOTE.—All figures expressed in thousands except Line 15.

What has been said of the net income budgetary procedure also applies in general to the budgeting of cash. Table 3 is the consolidated 1929 cash forecast for the X Oil Company and its subsidiaries. It is obvious that price fluctuations of crude and refined products will affect cash receipts, that is, collections from crude oil and refined products sales, and cash disbursements for crude purchases.

It has seemed necessary to outline the general budgetary procedure of the X Oil Company to this extent in order to establish a basis for considering the element of price fluctuations. We now address ourselves to that question. How does the X Oil Company which, like any other oil company, is itself unable to control the prices at which it buys its raw material—crude oil—and sells its finished refined products, proceed in forecasting prices?

TABLE 3.—X OIL COMPANY AND SUBSIDIARIES. FORECAST OF 1929 CASH RECEIPTS AND DISBURSEMENTS, APR. 30, 1929

NOTE.—All figures are expressed in thousands.

*Indicates red figures.

The task of forecasting prices is based primarily upon estimates of future supply and demand, both in respect to crude oil and its products. A careful study is made of current statistics and each month a detailed estimate is drawn up showing expected future production of crude oil, gasoline, etc., in the United States for a period of months ahead. These estimated figures are then compared with estimated demand, and after seasonal and other corrections are made, it is noted whether oil will be going to storage or withdrawn from stock. In this way, the statistical position of the industry is

constructed in advance, and from the preconstructed statistics conclusions as to probable price changes are drawn.

Under the X Oil Company procedure the price forecasts, as well as the forecasts of production, refining, and sales volumes, originate with the management representatives of the operating units. If we note Fig. 5 which shows this flow of price forecasts it will serve to fix the procedure in our minds. These forecasts flow to the headquarters Budget Department. This Department assembles the price estimates on a form represented by Table 4. This is submitted to the company's consulting petroleum economist for his comments and recommendations, and to the headquarters functional executives

FIG. 5.—X Oil Company flow chart of price forecasts

in general charge of the several operations to which the respective price forecasts apply for their recommendations. The form then goes, with these comments and recommendations, to the company's executive staff, where it is approved with or without revisions. The price forecasts thus approved are relayed by the budget department to the operating units from which the budget estimates originated, where the prices are applied to volume estimates, and in that way enter into the financial forecasts of net income and cash receipts and disbursements—first into the forecasts of the several operating departments and companies, and finally into the master forecasts of income and cash shown in preceding charts.

We are now prepared to consider the effect of a change in commodity prices upon the net income and cash forecasts of the X Oil Company. As a simple, concrete means of presenting this, let us assume that the price of all grades of crude produced or purchased by the X Oil Company were cut 15 cents a

barrel, and that a price reduction in gasoline of 1 cent a gallon on domestic dealer sales and of $\frac{1}{2}$ cent a gallon on bulk sales took place. Actually cuts in crude and gasoline are rarely simultaneous, reduction in gasoline prices usually lagging several days or weeks behind crude cuts or even taking place without change in raw material prices. We shall also assume that these price reductions continue in force for the remainder of 1929. We shall further assume that the inventories of the X Oil Company and its subsidiaries at Apr. 30 were carried at market prices, and that due to this price reduction in crude and gasoline these inventories must be written down to the new market price. This adjustment will be a charge to net income.

TABLE 4.—X OIL COMPANY AND SUBSIDIARIES. PRODUCING, REFINING AND SALES UNITS, 1929 ESTIMATED UNIT PRICES

a Product	b Unit	c	d e		f g		h i		j k		l m	
		Actual March	Apr.		May		June		July		Balance of year	
			Pres.	Prev.	Pres.	Prev.	Pres.	Prev.	Pres.	Prev.	Pres.	Prev.

Obviously these changes invalidate the forecasts of net income and cash dated Apr. 30, making necessary a revision thereof. This revision is undertaken by the headquarters budget department and is not a very complicated process, as will be seen from Table 5 which may be regarded as a working paper calculation of the effect of the assumed price changes on net income and cash estimates. In following the calculation on this form you will please note that the left-hand column represents net income and the right-hand column cash, and that the red figures represent decreases in net income and cash, and the black figures represent increases in net income and cash.

We note that over the balance of the year, i.e., May 8 to Dec. 31, the producing subsidiary estimates its crude oil production at 32 million barrels. A decrease of 15 cents per barrel on this production represents a shrinkage in income of \$4,800,000. The cash effect of this price change is measured by the portion of the production which is sold to other buyers than the X Oil Company; that according to our assumption is 50 per cent, or 16 million barrels, which at 15 cents per barrel reduction amounts to a decrease in cash revenue of \$2,400,000.

The assumed inventory of the A Producing Company at Apr. 30 is 3,000,000 barrels of crude, which because of the 15 cents price cut, must be written down

\$450,000. Thus the effect of the crude price change upon the A Producing Company has been to reduce the net income estimate, for the period May

TABLE 5.—X OIL COMPANY AND SUBSIDIARIES. CALCULATION OF THE EFFECT OF ASSUMED PRICE CUTS ON NET INCOME AND CASH

Assumptions:

1. Crude oil decreased 15¢ per barrel
2. Gasoline—domestic dealer decreased 1¢ per gallon, bulk decreased $\frac{1}{2}$ ¢ per gallon
3. Period affected—May 8 to Dec. 31
4. Inventories at Apr. 30, carried at market and adjusted to include effect of above price changes

NOTE.—Black figures represent additions and red figures* represent deductions. Figures in Columns c and d are expressed in thousands.

8 to Dec. 31, \$5,250,000 and to reduce the forecast of cash revenue \$2,400,000 for this same period.

The crude cut affects the C Crude Oil Purchasing Company favorably as to cash, in that the purchase program of 16 million barrels over the balance

of the year from outsiders will require \$2,400,000 less cash than if the crude price had remained unchanged. The effect upon the C Crude Oil Purchasing Company's net income—\$1,500,000 is measured by the write-down of 15 cents per barrel on the 10,000,000 barrels which are assumed to be in storage as of Apr. 30.

We now turn to the parent company, the X Oil Company, to complete the calculation of the effect of the crude price cut. It will be seen (line 11) that the effect of the 15 cents per barrel cut in cost of crude run to stills in the company's refineries from this date to the end of the year is to reduce this cost \$4,800,000, which means that net income will increase a like amount. The crude inventories, however, assumed to be 2,000,000 barrels at Apr. 30, must be written down \$300,000 to give effect to this price reduction (line 12).

Turning now to the gasoline price cut, it will be seen (line 7) that the one cent per gallon cut in domestic dealer sales of 535,000,000 gallons will reduce both income and cash (line 9) \$5,350,000, and that the $\frac{1}{2}$ cent per gallon price cut in bulk sales will also reduce both income and cash by \$750,000.

The remaining element which must be considered in calculating the effect of the gasoline price cut is the company's gasoline inventory at Apr. 30 of 75,000,000 gallons, which has been written down 1 cent, involving a reduction in net income of \$750,000.

By way of recapitulation, the net effect of these price changes on net income and cash is to decrease the A Producing Company's net income by \$4,800,000, which is offset by an increase in net income of the X Oil Company. That is to say, what the A Producing Company loses in net income through reduced oil earnings, the X Oil Company adds to net income through the reduction in the cost of its raw material.

The result of the crude oil price reduction on the consolidated net income is a reduction of \$2,250,000, all of which is due to writing down inventories to the new market level.

The gasoline price cut reduces net income \$6,850,000, of which \$750,000 represents a write-down of inventories and \$6,100,000 a reduction in sales realizations.

The combined effect of the foregoing upon net income is to reduce it \$9,100,000. It will be noted that cash is reduced \$6,100,000. The difference of \$3,000,000 between the reduction in net income and cash is due to writing down inventories in that sum.

It is interesting to note that the crude cut has not affected cash, for the reason that the reduction in accounts receivable of the A Producing Company is exactly offset by a decrease in the accounts payable of the C Purchasing Company.

We are now prepared to reconstruct the forecasts of net income and cash in accordance with the foregoing calculations. The elements which must be revised to reflect the effect of these price changes upon net income forecast (Table 6) are lines 5, 6, 7, and 8, and columns a, c, d, e, and f. You will note that what was the "present view for the year" on the Apr. 30 forecast, which then appeared in column e, now becomes the "previous view for the year" and appears in column f. For purposes of simplifying this explanation, the working sheet dealt merely with figures for the entire period from May 8 to Dec

31 whereas the actual process of revising the forecast, of course, involves breaking down this total change into the respective periods affected.

The effect of these changes in terms of the consolidated figures is to change an Apr. 30 forecast of May net income of \$2,675,000 to a loss of \$1,425,000. Three million dollars of this decrease is due to writing down inventories in this amount. The June estimate declines from \$3,150,000 to \$1,850,000, and the estimate for the balance of the year of \$13,675,000 becomes \$9,975,000; the total income previously estimated at \$28,125,000 now becomes \$19,025,000. After providing for taxes and preferred dividends, the amount available for common dividends is now \$11,742,000, as against the previous forecast of \$19,750,000. Stated in terms of estimated earnings per common share, we now have \$1.17 as against the former estimate of \$1.98, a reduction of 81 cents a share.

TABLE 6.—X OIL COMPANY AND SUBSIDIARIES. FORECAST OF 1929 NET INCOME, MAY 8, 1929

		a	b	c	d	e	f	g
		A Producing Company	B Pipe Line Company	C Crude Oil Pur- chasing Company	X Oil Company	Total (a to d)	Pre- vious View for year	1928 actual

14	Common dividends					10,000	10,000	10,000
15	Net income to surplus					\$ 1,742	\$ 9,750	\$15,000
16	Earnings per common share					\$ 1.17	\$ 1.98	\$ 2.50

NOTE.—All figures expressed in thousands except Line 15.

*Indicates red figures.

Table 7 shows how these price changes bear upon the cash forecast, the columns and lines marked by arrows indicate the periods and items affected.

Passing over any detailed reference to these, the net effect on cash is to reduce the Apr. 30 estimate of cash at the year end of \$25,000,000 to \$18,900,000.

In addition to fluctuations of crude prices and of the prices of gasoline and other refined products, which are the price fluctuations of primary importance, there are, of course, many other price fluctuations which, while secondary in importance, have nevertheless not always an unimportant effect on net income and cash of an oil company. Fluctuations in transportation

NOTE—All figures are expressed in thousands.

* Indicates red figure.

costs, for example, may have a very appreciable effect. Price changes also occur in the multitude of materials and supplies used in the production and refining of crude oil. Under the budgetary system of the X Oil Company, however, these minor price changes are reflected in the regular monthly revisions of forecasts.

The conclusions which are most pertinent to the subject are first, that while price fluctuations do complicate the process of budgeting, it is equally true that price fluctuations emphasize the need of budgetary control, and second, that sound budget procedure assures facility in revising forecasts and, where revision is simple, price or other fluctuations cause little concern to those who operate the budget.

CHAPTER III

INCORPORATION AND THE POSITION OF THE STOCKHOLDER

THE INCEPTION OF THE CORPORATION

By K. O'MALLEY, *Attorney, Western Electric Company, Incorporated*

Corporation Defined. A corporation is an association of natural persons authorized by the sovereign power of the state to act in its own proper person, as a legal entity, having existence, citizenship, and a domicile separate and apart from the persons who compose it and completely merging their individuality. The corporation is sometimes referred to as a "fiction of the law," the purpose of which is to enable a group of individuals to transact business in a more convenient way than would be possible if they retained their identity as individuals. It should be borne in mind, however, that the so-called corporate fiction does not merge the individuality of the members to the extent that they cannot, today, be recognized and held accountable as individuals when it becomes evident that they are employing the fiction for a fraudulent purpose. In a recent publication on the subject of the disregard of the corporate fiction, I. Maurice Wormser aptly states:

. . . in the present condition of the authorities a corporation will be looked upon by the courts as a legal personality, for ordinary purposes in everyday business transactions, as a general principle and until adequate reason to the contrary appears; but the fiction will be disregarded and the law will look to see the men and facts behind the fiction whenever it is employed "to defraud creditors, to evade an existing obligation, to circumvent a statute, to achieve or perpetuate monopoly, or to protect knavery and crime."¹

It need scarcely be stated that no fraud is deemed to be involved by virtue of the fact that individuals incorporate to avoid personal responsibility for debts, and that people do frequently incorporate for this express purpose.

The Advantages of the Corporation as a Means of Conducting Business. The principal advantages of functioning as a corporation rather than as an association of individuals are:

First, the Stockholders' Immunity from Personal Liability. Stockholders of a corporation are, in general, immune from personal liability for debts contracted by the corporation, the extent of their liability being the unpaid balance due on their subscriptions for stock. This personal immunity is

¹ "The Disregard of the Corporate Fiction and Allied Corporate Problems," p. 40, Baker, Voorhis and Company, 1927.

sometimes limited by the constitution or laws of a particular state, or because of the existence of special circumstances which estop an individual stockholder from denying the assumption of personal liability, but when a statute extends the personal liability of stockholders, it usually applies only to obligations of a particular nature designated in the statute, such as liability to operatives for services rendered, or liability for the unpaid balance due on stock of an insolvent subscriber. It is common for the state legislatures to impose personal liability upon stockholders of banks in an amount equal to the par value of their stockholdings in addition to the unpaid balance due on their subscriptions for stock.

Second, the Capacity for Perpetual Existence. A corporation as distinguished from an association of individuals, such as a partnership, has the capacity for perpetual existence, that is, the transfer of shares of stock by one individual to another and the consequent introduction of strangers to the membership does not effect a dissolution of the corporate body as it would in the case of a partnership.

Third, Functioning as a Separate Entity. The corporation is a separate entity distinct from the persons who may own its stock and control its destinies and, as such, is able in its own name to acquire and convey property; to enter into contracts; to sue and be sued; and to exercise such other powers as the legislature may have granted to it, in the same manner as a natural person may do. Although the acts of a corporation are of necessity performed by individuals, as its officers or agents, the individuals are merely the instrumentalities through whom the entity functions, and their acts are the acts of the corporation for which the corporate entity is responsible.

The Corporation Distinguished from a Partnership. A corporation and a partnership are two distinctly different types of organization. A partnership comes into being by mere agreement between the parties, while a corporation cannot be so formed but must acquire its existence by grant of authority from the state legislature. The members of a partnership do not lose their identity as individuals, there being no legal entity created as in the case of a corporation, and the business is transacted and the property owned by all the members jointly in their individual capacity. The retirement or death of one of the partners or the transfer of his share in the business, effects a dissolution of the firm, in the absence of provision to the contrary having been made in the partnership agreement, and the continuance of the business after that time depends upon a further voluntary agreement being entered into between the surviving partners. The reverse is true of a corporation, as has been stated above. Each member of a partnership is an agent for the firm with respect to matters within the scope of the partnership business, while a corporation acts only through its board of directors, or through agents to whom authority is especially delegated by the board. The members of a partnership are personally responsible to the extent of their private fortunes as well as their interest in the partnership business, for debts incurred by the firm, while no personal responsibility, in general, attaches to the stockholders of a corporation.

The Corporation Distinguished from a Joint Stock Company. The distinction between a corporation and a joint stock company is less clearly defined.

Basically the joint stock company resembles a partnership, for it comes into being as a result of the mere agreement of the members instead of acquiring its existence from the state, and no legal entity is created, the company being simply the sum total of its members. But in practical effect the corporation and the joint stock company are more nearly akin. The members of a joint stock company, like those of a partnership, are individually liable for the obligations incurred by the company, but the legislatures in many of the states protect the members of joint stock companies from liability until all legal remedies against the collective body have been exhausted. The legislatures may limit and, in some instances, have limited the individual liability of members of joint stock companies even further. A joint stock company cannot acquire or convey property, and cannot bring or defend suits in the company name, as a corporation may do. Dealing with property and participation in law suits must be in the individual names of the members, numerous though they may be. But property may be dealt with and suits instituted by an officer of a joint stock company as trustee for the several members, and this, for practical purposes is as effective as though the name of the company could be used. A joint stock company, in the absence of statutory provision, cannot sue one of its members, nor can it be sued by them because in bringing such a suit it would occupy the position of both plaintiff and defendant. The legislatures, however, in some of the states authorize the bringing of suits by a joint stock company against its members, and vice versa. There is, of course, no objection to suits in which a corporation and one of its stockholders are plaintiff and defendant respectively, owing to the fiction of the corporate entity. Another characteristic which the corporation has in common with the joint stock company is the fact of its acting through the official agency of a board of directors, and that the individual members of a joint stock company are not, as in the case of a partnership, agents for the body by virtue of their membership.

From the foregoing it will be observed that the distinction between corporations and joint stock companies may often be difficult of discernment, especially in jurisdictions where the legislatures have endowed joint stock companies with the essential attributes associated in early times only with corporations. In some cases the distinction has been so ill defined that the courts have differed in their opinions as to whether an association was a corporation or a joint stock company, and foreign jurisdictions have deemed as corporations, for tax purposes, associations recognized in their native state as joint stock companies.

The Purposes for Which a Corporation May Be Formed. As a corporation is purely a fiction of the law it follows that it can be created only for the purposes contemplated by the laws (sometimes referred to as statutes) of the state from which it is to acquire its existence. In some jurisdictions the language of the statute is very general, authorizing the formation of corporations "for the purpose of carrying on any lawful business or businesses of any kind or nature whatsoever," in which case there is no restriction as to the purpose for which a corporation may be formed excepting that it must be a purpose compatible with the constitution and general laws of the state and the United States. In other jurisdictions the language of the statute is

specific, enumerating the purposes for which a corporation may be formed, as: "Corporations may be formed for any of the following purposes: 1 . . . 2 . . . 3 . . . 4 . . .," in which case the purpose for which the corporation is being created must come within the fair import of one of the purposes enumerated.

Stock and Non-stock Corporations. In general corporations are divided into two classes: stock corporations and non-stock, or membership, corporations. Stock corporations are those having a capital stock, the shares of which are issued to the members, known as stockholders, in return for their contribution to the capital, and on which shares the company may make periodical payments, called dividends, which represent a part of its surplus. Corporations for profit are generally organized in this form. Non-stock corporations are those having no capital stock, and in which the membership is evidenced by a certificate which entitles the member to whatever privileges are accorded him by the company's Charter and By-laws. The membership form of corporation is utilized for ideal purposes, that is to say, for societies organized to render a social, religious, charitable, or mutually beneficial service.

The Function of Promoters. The individuals who undertake to organize a corporation are known as promoters. From the common usage of the word "promoter" it has perhaps come to depict in the minds of many, the zealous stock salesman who paints his bargains in all too glowing colors in an attempt to disarm the circumspect purchaser. In reality the function of promoters is of major importance. They are the individuals with whom originates the fundamental concept which is to be the motivating force of the corporate body. They have a unique idea of either commercial or ideal value, but one which can be realized only by the contribution of capital and/or services by many individuals. It is, then, for the realization of this fundamental concept that they promote a corporation. Promoters take care of the necessary formalities incident to the inception of the corporation, that is, they arrange for the preparation of the corporate charter (also referred to as the articles of incorporation of the certificate of incorporation); procure execution of the charter by the required number of persons, known as incorporators; submit the proposed charter to the Secretary of State or other officer designated by the statute; procure the certificate of incorporation from the state; obtain subscriptions to the capital stock; raise funds to cover expenses incurred pending commencement of the corporate existence; and enter into preliminary contracts.

Liability on Contracts Made by Promoters. Promoters may or may not be personally liable on contracts made on behalf of an intended corporation, depending upon the nature of their agreement with the contractor, that is, the individual furnishing the material or service desired. It is the general rule that if the contract is made in the name and solely upon the credit of the intended corporation no personal liability will attach to the promoters unless the contract is one which the corporation, when formed, has not the power under its Charter to make. But if the contract is made in the name and upon the personal credit of the promoters, (and this is sometimes necessary on account of the difficulty of inducing the extension of credit to a non-existent

company) the promoters are personally responsible for the performance of the contract, notwithstanding the fact that it was made solely for the benefit of the corporation. Promoters may be relieved of responsibility in such cases by the corporation's subsequently adopting the contract and entering into an agreement with the contractor assuming the sole responsibility for its performance.

Procedure Required in Forming a Corporation. Persons concerned with corporate management should be familiar in a general way with the steps necessary to bring a corporation into existence. As the legislature of each of the states of the Union outlines the procedure to be followed in creating a corporation under its jurisdiction, and as the details of the procedure vary in the different states, a résumé of the essential steps generally required by a majority of the states must suffice.

The Controlling Law: Special or General Act of the Legislature. The legislatures in the exercise of their sovereign powers may create corporations, either by special enactment, applicable only to a particular corporation, or by enacting a general law prescribing the conditions upon which any and all individuals may incorporate. The constitutions of a majority of the states at the present time, prohibit the granting of corporate powers by special act of the legislature, with specified exceptions, and require the legislature to adopt a general enabling act under which individuals may band themselves together as a corporation. A general enabling act is not necessarily a single law—it may be a series of laws, each of which governs a particular type of corporation. For example, a state may enact a general corporation law applicable to all types of corporations and separate laws applying specifically to particular types of corporations. A general enabling act eliminates the possibility of discrimination by the legislature for it amounts to a general regulation of the subject which is available to any and all persons who come within the terms of the statute and who comply with the conditions imposed thereby. Accordingly, the usual method of incorporating in this country is by compliance, on the part of individuals, with the general laws of the state in which the corporation is to be formed.

Notice of Intention to Incorporate. The first step necessary in forming a corporation under the general laws of some states is the publication of notice on the part of the incorporators of their intention to form a corporation.

Preparation of the Charter. The next step is the preparation of the proposed charter or, as it is sometimes called, the articles of incorporation, or the certificate of incorporation. The charter must be drawn with the utmost care and must include statements complying in every detail with the controlling statute and must be executed and acknowledged before a notary public by the incorporators or the directors named in the charter, or by such other persons as may be specified by the statute.

Contents of the Charter. The statements commonly required to be set forth in the articles of incorporation are as follows:

1. The name of the proposed corporation. The liberty of the incorporators to select any desired name is subject to whatever restrictions may be imposed by the statute. Thus, many states make it obligatory to include in the corporate name the word "Corporation," "Company," "Incorporated."

"Inc.," "Limited," or the like. A further restriction is that the name of an individual cannot be made a part of the corporate name unless he consents to its use. To avoid confusion and to prevent unfair competition most states forbid the use of any name similar to that of another corporation already incorporated, or registered to do business in the state, or a name previously reserved for an intended corporation.

2. The address of the office of the corporation in the state where the incorporation is proposed.

3. Reference to directors and to the original stock subscribers, or the incorporators. A statement as to the number of directors, (usually a minimum of three) which shall constitute the board, and the names and residences of those chosen to hold office for the first year, or until the first annual meeting of the members or stockholders, is usually required. In the case of stock corporations the names and residences of the original subscribers to the capital stock should be included, with a statement as to the number of shares subscribed by each, and in the case of membership corporations, the charter should set forth the names and residences of the incorporators.

4. The purpose for which the corporation is being formed. Most of the states require the charter to specify the purpose for which the corporation is being formed, the particular business it is intended to transact, and the powers and privileges that it proposes to exercise. As has already been stated, the purpose for which the corporation is being formed must be one sanctioned by the particular statute governing the incorporation and not repugnant to the Constitution or the general laws of the state or the United States.

5. Details regarding the stock. In the case of business corporations, as distinguished from corporations not created for pecuniary profit, it is usual for the statute to require a statement in the charter of substantially the following details regarding the capital and stock of the proposed corporation: The total authorized number of shares, the number of such shares that have no par value, the number of such shares that have a par value, and the par value thereof; a description of the several series and/or classes of shares, if the shares are to be classified or issued in series, and a statement of the number of shares in each class and/or series, and the designations, voting powers, preferences, the dividend, redemption, optional or conversion rights or restrictions, limitations or qualifications granted to or imposed upon the shares of each class or series; and the amount of paid-in capital with which the corporation will commence doing business.

If the corporation is to be a non-stock or membership corporation, it is customary to include a statement in the charter to that effect, irrespective of whether or not the statute specifically requires it.

6. The intended life of the corporation. A statement is included as to whether the life of the corporation is to be perpetual, or limited to a specified number of years, and if it is to be so limited, the number of years during which it is intended to operate.

7. Optional provisions. The statutes frequently specify that the articles of incorporation may include any further provisions which the incorporators may choose to insert regarding the regulation of the business and the conduct

of the affairs of the corporation, and considerable latitude is allowed to the incorporators in limiting or regulating the powers of the corporation or its directors, stockholders, or members, provided the limitations or regulations are not inconsistent with the enabling act or with the Constitution or general laws of the state.

8. Provision for the adoption of by-laws. It is customary for the Charter to provide for the adoption of by-laws to control the functioning of the corporation, whether or not the statute prescribes the inclusion of such provision.

Filing the Charter. When the proposed charter has been prepared in compliance with the requisites of the general enabling act of the state, it is filed with or submitted to, according as the statute directs, the Governor, the Secretary of State, or other ministerial officer designated by the statute. In some jurisdictions it must be accompanied by affidavits testifying to the amount of the capital already paid in, or the amount of stock already subscribed, and the extent of the payments made on such stock subscriptions.

Issuance of the License. The officer examines the charter, and having assured himself that it fulfills all the statutory requirements, he endorses it "filed," or "approved," or, as is required in some jurisdictions, issues to the incorporators a document known as the corporate charter or articles of incorporation, or certificate of incorporation. This document originates with the ministerial officer, but consists principally of a copy of the charter as proposed by the incorporators. The articles of incorporation must then be recorded at the place and within the time prescribed by the statute, and the recording fee and organization tax paid. Further mention will be made herein on the subject of taxes and recording fees.

Organization Procedure. The statutes generally prescribe a definite procedure to be followed by the corporation in perfecting its organization before it actually begins to function. The procedure outlined below is fairly representative of that prescribed by a majority of the states.

The Organization Meeting; First Directors' Meeting; Filing of Report of Organization. After the approval of the certificate of incorporation, and until directors are elected, the incorporators assume charge of the affairs of the corporation and, in the case of stock corporations, take such steps as are necessary to obtain subscriptions to its stock. A majority of the incorporators (in some cases any one incorporator) call the first meeting of the corporation at such time and place as may be designated in the notice. The statutes frequently require that the meeting be held within the state of incorporation. Notice of the meeting is published in a newspaper prescribed by the statute, or is sent to each of the incorporators and stockholders individually. At such meeting the incorporators, and, in the case of stock corporations, the subscribers to stock, perfect the organization by the choice of a temporary chairman and temporary secretary or clerk, and the election by ballot of the number of directors specified in its charter or required by statute. Subsequently a meeting of the directors is held, at which by-laws are adopted and officers elected. In several jurisdictions the statute requires as a condition precedent to the corporation's entering upon the regular conduct of its business, that the directors file with the Secretary of State what is known as a

report of organization containing various items of information testifying to the fact that the proper organization procedure has been followed. It usually contains statements such as that the directors and officers of the corporation have been duly elected and its by-laws adopted; and details as to the amount of stock subscribed and the extent of the payments made on the subscriptions.

Fees and Taxes Imposed by the State and Federal Governments. In the expenses necessarily incident to the creation and maintenance of a corporation, the fees and taxes imposed by the state and federal government play no small part. Therefore a word with respect to the nature and extent of the corporation taxes generally imposed should be of interest. There are various methods by which the states may secure revenue through the taxing of corporate interests, and in the absence of any regulatory provisions in the state constitution, the legislature may use its discretion as to which method it shall employ and also as to whether it shall employ one or several of such methods.

The Initial Fees and Taxes. *Incidental Fees.* First of all there are sundry small fees prescribed by the state to accompany the filing of documents and fees to reimburse the state for its services in performing such ministerial duties as the examination of, or issuance of, the certificate of incorporation, for furnishing certified copies of the certificate and for affixing to those documents the great seal of the state. These incidental fees usually aggregate from \$10 to \$35, depending upon the state of incorporation.

Charter Fee. The next initial fee prescribed by most of the states is one usually referred to as the organization or charter fee. In some jurisdictions the organization fee is graded according to the amount of the capital stock which the corporation is authorized by its charter to issue. In others it is graded according to the amount of the capital stock which the corporation intends to issue at once. As the rate varies in different jurisdictions it would be impracticable to make a general statement here as to what rate is specified, but the following are examples of the rates effective in three different states which will afford a general idea as to the probable extent of the organization fee.

1. 10 cents per \$1,000 on first \$1,000,000, plus 5 cents per each additional \$1,000 of authorized capital stock having a par value; and 10 cents for each 1,000 shares of the capital stock having no par value.

2. One-twentieth of 1 per cent of the authorized par-value stock; and 5 cents per share for no-par-value shares.

3. One-twentieth of 1 per cent of capital stock issued or to be issued at once; no-par-value shares taxed on the amount received or to be received therefor.

In practically every state in which the organization fee is graded the statute fixes a minimum amount to be paid, such as \$3, \$25, \$50, and some states fix a maximum also, such as \$150, \$600, \$3,000.

Federal Stamp Tax. A further initial fee in the form of a stamp tax is imposed by the federal government. Stock issued by the corporation is subject at the time of issuance to a stamp tax of 5 cents for every \$100 or fraction of \$100 of its par value, or, in the case of no-par-value stock, a stamp tax of 5 cents on every \$100 or fraction of \$100 of actual value. In the case of the actual value of no-par stock being less than \$100 the stamp tax is

computed at the rate of 1 cent for every \$20 or fraction of \$20 of actual value. In the case of stock which the corporation issues in the form of a certificate representing more than one share, the measure of the tax, in the case of par-value stock, is the face value of the certificate and not the face value of each separate share which it represents; and the measure of the tax in the case of no-par-value stock is the actual value of the certificate and not the actual value of each separate share which it represents; and this is true however large may be the number of shares a certificate represents.

Annual Fees and Taxes. In addition to these incidental and organization fees there are annual taxes to be paid. The states frequently impose two, three, or four kinds of annual corporate taxes, concurrently effective.

Annual Registration Fee. First, there is the annual registration fee which a few of the states prescribe. This is sometimes a fixed sum, such as \$15; or it may be based upon the amount of paid-in capital stock or other factor which the legislature may designate.

Annual Franchise Tax. The annual franchise tax (sometimes referred to as the license tax) is perhaps the most commonly employed. Occasionally it is fixed at a flat amount, sometimes as low as \$1, but more generally the states require that it be computed upon one or the other of the following bases: the amount of authorized capital stock; the amount of paid-up capital stock; the amount of stock issued and outstanding; the amount of stock subscribed, issued, and outstanding; or that the tax shall be computed according to one of two given methods, depending upon which will afford the state the advantage in revenue; or upon the amount of the corporate capital, property, and assets located and employed within the state; or upon an allocation of the net income of the corporation for the tax year represented by assets employed or business transacted within the state. Where the franchise tax is computed upon one of the above bases, the rate of tax is often graded according to the amount of stock, or income, or the value of the corporate property and assets, as the case may be.

Where the tax is based upon the amount of stock, or income, or the value of the corporate property and assets, the states usually fix a minimum annual tax, such as \$5, \$10, \$25, and some states fix maximum tax also. The rate of tax in different states, and the fixed maximum, if any, vary so sharply that a general statement cannot well be made as to the probable rates and amounts. Suffice it to say here that the lowest maximum franchise or license tax (in jurisdictions where the rate is graded) fixed in any state at the date of this writing is \$100, and the highest maximum, \$50,000. The fact of a maximum franchise tax being fixed affords an advantage to corporations employing very large capital, as will be noted later.

Other Annual Taxes. Other annual taxes sometimes imposed by the states are the income tax, the corporate excess tax, the excise tax, capital stock tax, occupational license tax, moneyed capital tax, and corporate loans tax.

Federal Income Tax. The United States Government imposes a further annual tax, known as the federal income tax. This tax is computed upon the basis of the entire net earnings of the corporation during the federal tax year, and is figured at the rate of 12 per cent. An exemption of \$3,000 is allowed if the earnings of the corporation are \$25,000 or less.

Matters to Be Considered in the Choice of a State. When a group of individuals contemplate banding themselves together into a corporate body, it becomes necessary to determine in what state they will apply for incorporation. At first blush it would seem natural to apply for incorporation in the state in which the incorporators reside or the state in which the corporate interests are principally to be located, but this is not necessarily the case. The structure of the corporation, the powers with which it may be endowed in its charter, and the initial taxes, and some types of annual taxes imposed upon it, as well as the qualifications of the incorporators and directors, are controlled exclusively by the law of the jurisdiction from which the corporation acquires its existence, and the corporation may be afforded a decided advantage by the laws of one state as against another.

There are several statutory provisions likely to affect the interests of the corporation, favorably or otherwise, depending upon the type of corporation being formed, the nature and extent of its proposed business operations, if it is a corporation for pecuniary profit, and the identity of its incorporators and directors. Such statutory provisions should be considered by the incorporators before determining in what state they shall apply for their charter.

Number and Qualifications of Incorporators and Directors. Most of the states prescribe a minimum of three incorporators and a minimum of three directors, but in a few jurisdictions no minimum number is specified. Some states prescribe also personal qualifications for incorporators and directors, such as that they shall be residents of the state, or citizens of the particular state or of the United States, or that they must be subscribers to the stock of the corporation. Others impose no such qualifications.

Organization and Stockholders' Meetings; Place of Holding. The meeting of the incorporators to perfect the organization is frequently, though not in every case, required to be held within the state. Some states permit stockholders' meetings to be held either within or without the state, while under the law of others a stockholders' meeting held outside the state would be invalid.

Personal Liability of Stockholders. Although it is the general rule that the extent of a stockholder's personal liability to creditors of the corporation is the unpaid balance due on his subscriptions for stock, there are a few jurisdictions where further liability is imposed. For example, one of the states renders stockholders personally liable for all obligations incurred by the corporate body unless their liability is specifically limited by a provision to that effect in the charter. Another state renders the solvent stockholders liable for the unpaid stock subscriptions of any insolvent subscriber, and a few states impose personal liability for labor performed for the corporation.

Cumulative Voting. Cumulative voting by the stockholders is permitted in many jurisdictions, though not universally. The following will serve as an illustration of what is meant by cumulative voting: Assume that the by-laws of a corporation reserve to the owner of each share of stock the privilege of casting one vote for each nominee for the board of directors. If the board is composed of, let us say, fifteen members, each share of stock may cast a total of fifteen votes for the board. In jurisdictions where the statute permits of

cumulative voting the charter or by-laws may reserve to the stockholder the right to cumulate his fifteen votes in favor of one or more of the nominees. This cumulation of the votes represented by a single share of stock is known as cumulative voting and, as stated above, is not permitted in all jurisdictions.

Regulations Affecting the Stock of the Corporation. The statutes frequently fix a minimum amount of authorized capital stock which the charter must stipulate; or they fix a minimum amount of the stock to be subscribed; or the amount to be paid in before the corporation can begin to function. If the activities and the assets of the proposed corporation are to be very limited, the incorporators would probably avoid organizing in such jurisdictions. Occasionally the statutes prescribe a limit as to the number of different classes of stock a company may issue. If the business activities are to be extensive and the capital large, the incorporators would no doubt prefer a state that imposes no limitation as to the number of classes of stock permitted.

Limitations as to the Amount of Indebtedness to Be Incurred and the Amount of Stock to Be Purchased. Only a few of the states specify limits as to the amount of indebtedness a corporation may incur, or as to the amount of stocks and bonds of other corporations that it may purchase, and where such restrictions are imposed they apply only to particular kinds of business. However, if a restriction of this nature is imposed it may influence the incorporators to organize elsewhere.

Comparative Tax Rates The corporation taxes are more moderate in some states than in others. Some states for example do not exact an organization fee. In others no annual tax is imposed, or there may be only one kind of annual tax imposed in a given state, as against two, three, or four in other states. Further, though one or more kinds of annual taxes may be effective, the rates may be lower in one state than in another. One state may fix a maximum organization and/or annual tax, while in another there is no tax limit. The lower rate of tax, or the fact that a maximum figure is set, would afford an advantage to the corporation, especially to a large corporation. By way of illustration, one of the states which grades its annual license tax according to the amount of the paid-in capital stock, specifies a maximum annual license tax of \$1,000 to be paid by corporations whose paid-in capital stock exceeds \$6,000,000. In the jurisdiction referred to, corporations having a paid-in capital stock in excess of \$6,000,000 enjoy an exemption from tax on the excess.

Basis upon Which the Tax Is Computed. The fact that a state bases its annual franchise tax upon the capital, property, and assets of the corporation employed within the state usually operates to the advantage of the corporation. The reason is that states in which the franchise tax is so computed usually stipulate that the franchise tax shall be in lieu of the property taxes imposed by the municipalities or counties, which local taxes invariably are computed at a higher rate.

Fund from Which Dividends May Be Declared. Another factor to be considered in the choice of a state is the payment of dividends. Some states prohibit the payment of dividends out of any but earned surplus, while others permit their payment from a fund which combines surplus and earned surplus.

Annual Reports Required. The preparation of the type of annual tax reports usually required to be made is a laborious and complicated task and discloses minute details of the company's financial affairs. It is sometimes deemed an advantage to incorporate in a jurisdiction which prescribes a comparatively simple form.

Qualifying the Corporation in Other States.—Not infrequently corporations organized under the laws of one state desire to transact business in one or more other states. If a corporation operates in any state other than that in which it was organized, it is regarded in that state as a foreign corporation. The legislature of any state may, and usually does, require as a condition upon which foreign corporations may transact business therein, that they first obtain a license or certificate from the Secretary of State to do so, and that they designate either an agent residing in the state or some public officer of the state, upon whom process may be served by persons in the state who desire to institute legal proceedings against the corporation; also that the corporation maintain an office within the state. The statutes generally provide that the license to do business within the state shall be granted to foreign corporations upon their filing with the Secretary of State the certificate of incorporation granted to them in their native state. It is also within the legislative discretion of a state, subject to its constitution, to impose initial license fees and annual taxes as a condition upon which foreign corporations are authorized to transact business within the state; and such initial fees and annual taxes are customarily imposed.

The foregoing general statement of the steps that must be taken to form a corporation will give to those confronted with the task of creating a corporation, an intelligible outline of the matters their attorneys will want to discuss with them before drafting the legal documents that are to accompany their formal application to the state for the inception of the corporation.

STOCKHOLDERS: THEIR RIGHTS AND DUTIES¹

By A. A. BERLE, JR., *of the New York Bar; Associate Professor of Law, Columbia University*

What Is a Stockholder? The stockholder has changed his position in American financial life so radically that the old rules no longer apply. Originally he was supposed to be a kind of modified partner in a small enterprise,

¹ Among the significant books in this field are:

VEBLEN, THORSTEIN, "Absentee Ownership," The Viking Press, New York, 1923.

usually a business man of means, able to take care of himself, and to take active part in the counsels of his corporation. During the past generation this situation has almost completely reversed itself. There are about 5,000,000 persons in the United States who today own stock (the estimate of 15,000,000 stockholders sometimes made is entirely too high); and the number is steadily increasing.¹ An overwhelming majority of these are "little people," that is, members of the investing public who own small blocks of stock, who know little or nothing about the corporate activities; whose advice is not sought in running the corporation and probably would be worth little if it were given. Stock is bought by most people as an investment; but the stockholder does not consider himself a responsible party in the business of his corporation. He trusts implicitly to the corporate management; his function is merely to contribute the capital, or to buy the participation of some one who has already contributed such capital.

This system in the aggregate virtually amounts to a new form of property tenure.² Roughly 40 per cent of the industrial wealth of the country (meaning thereby the national wealth excluding that proportion which is invested in government owned property and agricultural property, and a further deduction for certain real estate values) is represented by corporate securities actively traded in on the stock exchanges. Substantially more than half of this percentage is represented by stocks. The market valuation of such stocks varies widely and is incapable of accurate estimate; a probable figure (as of January, 1931.) is about \$65,000,000,000. This valuation bears only an oblique relation to the actual value of the underlying corporate property. It is an appraisal of the value of the shares as shares.

Many persons are, as a matter of economics, stockholders without knowing it. Thus, a man who holds life insurance really has a stake in an investment list owned by the insurance company; this frequently includes very large amounts of stock. He does not figure in business or in law as a shareholder at all. Yet he is vitally affected by the management of the corporations whose stock his insurance company holds. To a less degree this is true of bank depositors, investment trust shareholders, and participants in all institutions which collect savings. In its aggregate, the form of property tenure known as stock holding has become the type method by which industrial property is held in the United States. In its aggregate, the form of property tenure known as stock holding has become the type method by which industrial property is held in the United States.

In the aggregate also, the number of publicly financed corporations tends to grow steadily smaller; or, more accurately, concentration of wealth in the hands of the large corporations is steadily increasing. For instance, if the present rate of trend continues, substantially all of the industrial wealth of the country will be held by perhaps a dozen corporations in another century; and at that time the overwhelming bulk of the savings of the country would be invested in corporate securities. At present roughly 50 per cent of the savings of the country funnels into corporate securities; in gross figures this

¹ Estimated by Gardiner C. Means.

² *American Economic Review*, p. 54 ff, March, 1930.

amounts to approximately half of the monthly savings of nearly \$700,000,000, after excluding so much of savings as are needed for purely refunding purposes.

This means that the property structure of the country is rapidly reorganizing itself from a situation in which the individual invests money in his own business and expects to manage it, to a situation in which an individual invests his savings in a corporate enterprise and almost entirely loses control over it. To put it differently, ownership and power over property are largely divorced.

Technically, a stockholder is one who has subscribed for a share of stock (that is, agreed to purchase it on original issue); or, who has purchased a share of stock and caused it to be transferred into his own name. The corporation is obliged to regard as stockholders only those whose names appear on its books either as subscribers or actual owners.

Financially, the shareholder is a contributor of capital; but he is also something more. He is the best possible source of new capital. Accordingly, financial management today aims to keep the stockholder in a frame of mind to contribute additional capital. One of the cheapest and most satisfactory forms of financing is sale of stock through the issue of "rights" to subscribe to additional stock, which rights are distributed rateably among the stockholders' list. In the case of many older companies, new stock issues are obliged by law to be offered to stockholders rateably; but even where this is not the case, many corporations have found it good financial practice to raise additional capital in this way. Sometimes the corporation can thereby dispense with the services of an investment banker; the American Telephone & Telegraph Company, for example, has been able to raise new capital at the rate of roughly \$100,000,000 a year for a considerable period of time in just this manner. Corporations must go to the public for their capital; the aggregate of their stockholders' list is a little "public" which knows the corporation and which the corporation knows; and this financial goodwill is an instrument of great value.

As a matter of law, the stockholder has certain rights and duties hereinafter discussed. These may be summarized by saying that the stockholder is, in effect, the beneficiary of a very loose trust. Technically, law does not recognize him as such, though there is a growing weight of authority leaning even towards this technical result. Financially, he is in the position of having handed over savings to the corporation to manage for his benefit, and having surrendered almost absolute power to the corporate management, the implied understanding is that the management will handle this capital for his benefit and will pay him a proportion of the profits when it seems expedient to do so. As a matter of law the corporation and not the stockholder, has legal title to the corporate property. The stockholder, like the beneficiary of a trust, has only a claim against the persons who actually manage the capital; a claim based on the understanding that they will deal fairly and equitably with his property.

Classification of Stockholders. Unless something to the contrary is said in the certificate of incorporation, *all shares of stock are equal*¹ and must be

¹ MACHEN, "Modern Law of Corporations," Section 517, 1908, an old book, still the best in the field.

dealt with equally. If any difference is to be made, the corporate charter must state exactly what that difference is. In practice this means that unless there is to be only one class of common stock, the charter must "classify" the stock, setting out the respective rights, preferences, and disabilities of each class of stock. This privilege has been widely availed of; stock of almost every conceivable description can now be found in the markets. In general, however, certain distinct classifications appear.

Limited Preferred Stock. This is stock issued under an agreement that it will, in the event of dissolution of the corporation receive a stated amount, and no more, payable before the junior securities receive anything; also, usually, that it will receive dividends up to a certain amount; and no more, also payable in preference to dividends on junior securities. There may, of course, be preferred stock of various priorities; first preferred, second preferred, third preferred, and so forth. In this case the preferred stocks take rank according to their various priorities. The distinguishing characteristic of this kind of security is its limitation in all respects; they imply a sacrifice of possible large participations for a supposed security of principal and income.

Modern financial practice requires that limited preferred stocks should be redeemable, this is, that the company shall be able to retire preferred stock either in whole or in part when it chooses. This permits retirement of preferred stock when interest rates are low and the substitution of a security bearing a lower yield. Managements which have not observed this rule frequently find themselves in the position of having to bear the burden of a 7 or 8 per cent preferred dividend rate at a time when it would be profitable to pay out the preferred stock and substitute a 5 or 6 per cent issue.

Participating Preferred Stock. This is stock preferred over junior issues, usually both in distribution of assets and in dividends up to a certain point; but carrying the right to a further participation in income or in assets on dissolution according to some scheme worked out in the charter. Thus, a participating preferred stock may be entitled, on liquidation, to receive say \$50, in priority to junior issues; and to have a cumulative dividend of \$3 per share payable in priority to any junior dividends; but after it has received such cumulative preferred dividend, it then receives an additional dividend per share equal to any dividend declared on the common stock. The variations in this type of stock are unlimited. They are typically used in the baking companies (Continental Baking, General Baking, etc.) and are widely known elsewhere. They are sometimes called "class A" rather than "preferred." In practice, thus far, participating preferred stocks have not worked out well; the security of the preference is frequently illusory; and their extra participation is apt never to be realized. They were popular in 1927, 1928, and 1929.¹

Non-cumulative Preferred Stock. This is preferred stock, usually receiving a fixed amount on dissolution of the company, in priority to junior issues; but with a dividend payable in any year only if earned and declared by the board

¹ Discussed in BERLE, "Studies in the Law of Corporation Finance," Callaghan & Co., Chicago, 1928.

of directors. There is a controversy as to the dividends on this class of stock, the New Jersey courts holding that when such dividends have been earned they must be declared or, if not declared, they will pile up and must be declared later; though such dividends need not be declared or paid unless earned. The Federal courts apparently hold that if the board of directors fails to declare the dividend, whether or not it has been earned, a non-cumulative shareholder simply loses his dividend for the year in which the omission is made; though the question has not been squarely decided whether surplus so piled up may ever be paid out to junior shares. Under the latter theory non-cumulative preferred stocks are far less desirable than common stocks, since by failing to declare dividends although earned, for a period of time surplus can be built up, and subsequently this surplus can be declared out as dividends to the common shares, after declaring merely one full year's dividends to the non-cumulative preferred. On this theory the directors have an apparently absolute right to make the non-cumulative preferred really junior earnings to the common stock.¹

This stock must be distinguished from the usual cumulative-dividend preferred shares, whose dividend, if not declared in any year (whether or not earned), piles up. Before any dividends can be paid on junior issues, all cumulated arrears of dividends must be declared and paid.

Not infrequently, on all classes of preferred stocks, there are provisions giving the preferred stockholders the right to elect a majority of the directors if default has been made in dividends and is continued for a stated period.

Common Stock. The common stock is the standard form of equity security, that is, it is the typical junior stock, entitled to all of the earnings and all of the assets of the corporation after providing for prior dividend charges and preferences. The rapid increase in value of standard common stocks led a number of analysts, notably Edgar Lawrence Smith, in 1923 and 1924 to suggest that the stocks were a better investment medium even than bonds, since the appreciation in market value and the increase in dividends more than made up for the risk of fluctuation in market values and the danger that the stock might be wiped out through failure of the corporation.² This analysis, which is as true in 1931 as it was in 1923, has been somewhat discredited by the collapse of 1929-1930; unnecessarily, it would seem, since even at the low levels of 1930 most standard common stocks were selling far in excess of their prices in 1921. But there is involved in the analysis an assumption that the investor shall not buy in the top third of the business cycle, unless he is prepared to hold his investment not less than fifteen years. Most investors cannot predict their necessities so long a time in advance; this is peculiarly true of the small investor.

Common stocks commonly are entitled to vote, and usually this class of stock controls the corporation.

"Split" Common Stocks. The modern corporate structure has developed a division of common stocks into classes (class A common and class B), though

¹ BERLE, "Studies in the Law of Corporation Finance," (cited above).

² SMITH, EDGAR LAWRENCE, "Common Stocks as Long Term Investments," The Macmillan Company, 1924.

BADGER, R. E., "Investment Principles and Practices," Chap. 11, New York, 1930.

such practice is far less popular than it was up to November, 1929. This involves a division of rights between two classes of common stock, each of which participates, but one of which enjoys different or greater rights than the other. Thus the Dodge Motor Company, prior to its absorption by Chrysler, split its common stock into class A and class B, class A having exactly the same rights as class B except that it could not vote. Some of the utility companies have worked out split stocks, one class of common stock receiving two-thirds of the income as a class and the other receiving one-third of the income as a class. By manipulating the number of shares outstanding in each class, the directors thereby obtain a very wide power in routing the ultimate destination of the dividends which the company will pay. Thus, in the utility example given above, by issuing many shares of class A common entitled to two-thirds of the income, and limiting the class B to a very few shares outstanding, the participation of the class A shares may be very much diluted. This is even more true where the division is not between classes as such, but is dependent on the number of shares in each class. In that event, by multiplying shares in one class and not in another, the entire appropriation of income received by any group in the corporation may be varied.¹

The device was used widely in 1925 to 1926 to segregate voting rights to a very small class of common stock, thereby enabling the management to maintain continuous control. The New York Stock Exchange, however, ruled that it would not list common stocks without a voting right; the New York Curb with some exceptions followed suit; and the device became unpopular.²

Stock Purchase Warrants. Technically, these are not stocks at all. They are options issued to outsiders granting them the right to purchase authorized but unissued stock of the corporation at a price stated in the warrant. They may run for any period of time; the popular type at present runs for many years or even perpetually. The value of such warrants cannot be ascertained; and no accurate method of their appraisal has been worked out. It seems to be conceded that the values accorded to such warrants by the markets up to 1930, were unduly high. Until they have survived a full business cycle there will not be adequate data on which to base a judgment. They cripple the company in financing, since it becomes difficult to reduce the capital stock; the price of the stock when it is above the warrant price tends to be depressed; an unstable market situation may always be created by the exercise of warrants and sale of stock; and the value of the warrants and the time of issue can be fixed only arbitrarily without reference to their real significance and to the corporation and its shareholders when they are finally exercised. This is peculiarly true where a corporation has issued several times as many warrants as it has shares of stock outstanding (e.g., American & Foreign Power Co.). One theory is that perpetual warrants will never be exercised but are mere gambling counters. Use is frequently made of such warrants to com-

¹ See for an interesting example the capital set-up of Associated Gas & Electric Company. The participation features are given in Moody's *Manual of Utilities*.

² This was due to an attack on the device by W. Z. Ripley of Harvard University subsequently embodied in his book, "Main Street and Wall Street," Little, Brown, and Company, 1927.

pensate promoters and bankers (for instance, Pennroad Corporation, Niagara Hudson Company, etc.); but they are sometimes sold for cash to provide additional capital. They represent equity securities having the greatest possible risk; and, in theory at least, the greatest possible appreciation. Their legal status is not defined; the question has never been raised in the courts as to whether a corporation can use its surplus funds to buy outstanding warrants.

The Stockholders' Position in the Corporation. Originally stockholders were the dominant group in a corporation, since they elected the board of directors, generally every year, and had an active influence on the management. With the advent of classified stock, this position was weakened; preferred stocks, at least as long as they were secure, had little interest in the situation, more significantly the common stocks had an interest adverse to the preferred. Particularly where the common stock represented little or no investment, management representing the common stock would take long risks in the hope of large profits; preferred shareholders, on the other hand, would seek conservative management and security of dividend. The device of non-voting common stock divorced even the common shareholder from the management; and quite aside from the device, this result has in practice been achieved in any case wherever the common stock is widely dispersed. In such case the preferred shareholders form one group more nearly analogous to bondholders; the common shareholders another group; and the "management," including the titular officers, and directors of the corporation, and an individual or group having perhaps a minority block of stock but a position of influence known as "control," together formed a third group. The interests of any of these groups may be adverse; not infrequently the management may have interests adverse to the entire group of stockholders, though this is, of course, an unhealthy situation which well managed corporations seek to avoid.

The modern corporate charter will contain as complete a grant of absolute power to the board of directors as is permitted by the statute of the State of incorporation. In the so-called "liberal" states—notably Delaware—these powers are so broad as to permit activities which would virtually amount to confiscation of the stockholders' property.¹ It does not follow, however, that these powers can be safely used, even though the corporate papers and the statute appear to grant them. In the first place, it is not good policy to set up a feeling that the management is arbitrary in dealing with its shareholders; this makes further financing of the stockholders' list difficult, and it leads stockholders to distrust their management and to seek some organized method of upsetting the control. Second, despite the absoluteness of the power, courts of equity will usually enjoin the use of the power where the thing done is unconscionable. For this reason stockholders have a passive position with which a management must always reckon; no less so because the management

¹ The writer, having found himself unable to agree with the Committee to Draft the Delaware Corporation Law in 1929, filed in substance a minority report indicating the dangerous possibilities of the Delaware law; see "Investors and the Revised Delaware Corporation Act," *Columbia Law Review*, May, 1929.

will not directly know of the sentiment of the shareholders until it breaks out in some kind of direct attack.

Further, certain kinds of activities must be approved by vote of the shareholders. Principal among these are the sale of the assets of the corporation as a whole (this usually must be approved by a majority or in some cases a two-thirds vote); in certain states a mortgage of the corporate property must be so approved; amendment of the corporate charter changing the rights of shareholders, or increasing or decreasing the authorized stock must always be consented to. Consequently, whenever major changes are under way the management is always faced with the necessity of obtaining a sufficient number of proxies from shareholders to permit the action desired; and where there is distrust in the management these proxies are difficult to obtain. The natural inertia of shareholders in giving proxies or in voting at all is a difficulty in any event; where to this is added a fear that the management is adversely interested or is arbitrary, the liberty of action of the management may be seriously crippled.

The precise position of the shareholder in economics is, at the moment, a matter of debate. Certain economists insist that a shareholder is only a supplier of capital. He ought not, therefore, to expect any more than a return equal to the interest on his money, varied up or down according to the risk he assumes. Legally, on the other hand, the stockholder is the owner of the enterprise and all accretions of value belong to him. The justification for the economic view is that the shareholder of today, unlike the owner of yesterday, does not add to his capital the quality of management and labor; he, therefore, should not expect the entire accretion to his property. The argument in favor of the legal position is that if the accretions by way of profits do not belong to the shareholder, and the management attempts to absorb them, there is a violation of the old principle of private property; and possibly also the danger that the management will successfully attempt to loot the corporate properties, leading to a wholly unhealthy business situation. In practice, managements do absorb a portion of the corporate profits at the expense of their shareholders, largely through devices such as side operations; issues to themselves and their friends of low priced securities; market activities in stocks of their companies and the like; but these activities seem not to be very great in proportion to the whole corporate assets. Since only a few of the companies (Bethlehem Steel, Standard Oil of New Jersey, etc.) have adopted the system of frankly paying to the management a share of the profits of the enterprise, American business is fairly open to the charge that no sufficient means exists by which a corporate management can be adequately paid for the value of its services. Obviously, a healthier situation will exist when the European system is adopted by which a percentage of net profits is set aside for and turned over to the management. Such arrangements when made must be disclosed and openly known, to avoid criticism. Meantime, the adverse position of the management (which naturally seeks compensation), as against the stockholder (who supposes he is getting the entire profit of the business) must necessarily continue. It should not be driven to seek pay from market manipulation or side transactions. This is one of the outstanding problems in corporate management today.

Stockholders' Rights.¹ The foregoing principles suggest the basis for the various rights which a stockholder at least nominally has. Such rights, while they exist in law, are by no means necessarily available for all shareholders, especially small ones, since the expense of enforcing most of them is prohibitive. They can, in practice, be enforced only where there is rebellion against the management, a stockholders' committee is formed, and a war chest provided. The position of the stockholder is practically far weaker than his technical legal rights would indicate.

Legally a stockholder is entitled:

To subscribe to a ratable share of any new stock issued by the corporation. This is the so-called "preemptive right" and is the basis for the "rights to subscribe" issued by the old line companies such as the American Telephone & Telegraph Company. The underlying theory is that a stockholder has a right to maintain his proportionate voting control and also his relative participation in the assets and earnings of the company. Accordingly, the law requires that on the issue of new stock, or of options to buy new stock on securities convertible into stock, the management must offer every shareholder the right to subscribe to his proportion of the new offering. Certain states require this only where the charter is amended and the authorized but unissued capital stock is increased. The right works out well enough where only one class of stock is outstanding. But where the capital structure is complicated, questions of great difficulty arise. In general, a limited preferred stock is not entitled to subscribe to an additional issue of shares of common stock. In general also, common stock is not entitled (and does not greatly desire) to subscribe to additional issues of preferred stock. The law is in hopeless confusion in dealing with split common stocks and participating preferred stocks.²

For this reason and others, many corporate charters contain clauses by which the stockholder "waives" in advance his so-called preemptive right.

To have any new or "treasury" stock at a price which will protect his interest. On the issue of new stock, the management is obliged to exact a fair contribution from the incoming shareholder. Where the stock has par value, it is required to charge not less than par for the stock, save in exceptional circumstances such as where the corporation is threatened with insolvency and can obtain the money in no other way. Even here it is not a safe procedure. The price must be paid in cash or property of a form approved by the statute under which the corporation is organized. Future services cannot be used to pay for stock; and where existing property or past services are used, the directors must pass a resolution evaluating the property; such valuation must be made in good faith, else there is a danger that the stock will be held to have been under-paid.

¹ It is attempted here to summarize generally rather than to enter into an extreme and technical analysis of shareholders' rights. The legal materials are collected in Berle, "Cases and Materials in the Law of Corporation Finance," West Publishing Co., St. Paul, 1930.

² See A. H. FREY, "Shareholders' Preemptive Rights," vol. 38, p. 563, *Yale Law Journal*, 1929.

Where the stock is without par value (so-called "no-par" stock), there is no minimum requirement of payment. The directors must there determine what price adequately protects the old shareholders—they cannot, of course, be required to fix a higher price than the stock will sell for—and they must act fairly in the transaction. *Prima facie*, "no-par" stock cannot be sold to two groups at the same time at different prices; and wherever no-par stock is so sold, it must appear that the group paying the lower price is adding some element of strength to the corporation justifying their being allowed to come in at a price lower than that charged other subscribers. This is sometimes known in law as the "rule of equitable contribution." Likewise, no-par shares cannot be sold at a price so low that the incoming shareholder virtually attracts to himself a portion of the assets formerly belonging to the old shareholders.

To have dividends declared to him when the corporation does not need the accumulated surplus. While the law is extremely flexible as to when dividends must be paid, unreasonable accumulation of earnings, or failure to pay dividends for purely arbitrary reasons (as, to "freeze out" shareholders, or permit directors to buy at a low price) is not allowed. A stockholder can sue to compel payment. In practice this right does not amount to very much, since the judgment of the directors as to whether the corporation needs the money for additional expansion is almost absolute, and courts are not in a position to revise the judgment of the managers in this respect.

To have the management run the corporation impartially for the benefit of the shareholders. This also in practice is not easy to enforce. Nevertheless, a management is not legally allowed to run the business of the corporation primarily to forward side interests, or to favor one group in the corporation as against another. This has become an issue of great importance: as, where a banking group uses an investment trust either to take up the sale of the issues it finds difficult to sell, or to purchase control of another company so that the banking group may acquire power over that company; etc. A notable instance of this was the handling of the Denver and Rio Grande Railroad, prior to its reorganization and its use of funds to acquire and dominate other railroads. The Interstate Commerce Commission raked over this situation, vigorously criticizing the Gould management on this score. Similar criticisms were leveled, after its failure in 1930, against the Bank of United States.

To non-discrimination between shareholders. It is a fundamental rule of corporation law that all shareholders in the same class must be treated alike. Sometimes this raises problems: the British General Electric endeavoured to issue rights to subscribe, but limited them to British shareholders. The American shareholders vigorously contested this and the management found it necessary to recede from their position. So wherever stock dividends are issued, they must be of the same kind of stock to all shareholders; wherever stock is split up or changed in form, the change must affect all holders alike.

To retain unimpaired the contract position of his share, except where emergency requires its change. This also is a difficult right to assert. Not infrequently after a corporate structure has been set up, it is desired to change the rights

of certain shareholders, as, to put a prior preferred stock ahead of a first preferred stock; or to change the preferences of the preferred stock; or the like. *Prima facie*, this cannot be done where the change is material (in any event it requires the assent of a majority of the shares affected); even a minority stockholder may object. If, however, the management is proceeding under an appropriate power to amend the charter, and is able to make a showing that the situation of the corporation requires the change; and it appears that no class of stock is being unduly sacrificed to another class of stock, then the change will be permitted. In different states the right is differently applied; the stockholder's position is rigidly maintained in New Jersey, and only laxly maintained in Delaware.

To have his share of stock appraised and to be paid out in cash in the event of a merger or sale of the assets. Where the corporation merges with another, or where it sells its entire assets, a number of states provide that the shareholder who has objected may demand that his shares be appraised and that he be paid out in cash. This is designed to prevent the management, acting under a majority vote, from forcing the shareholder to take stock in a different or merged enterprise. The right is a new one and not thoroughly tested; appraisal proceedings have proved more difficult for shareholders than was originally supposed. The right to appraisal which is derived from statute and does not exist in all states, does not prevent the shareholder from objecting to the merger or sale and securing an injunction against it; it is a "cumulative" right, that is, a right which he has in addition to his legal right to prevent the merger if it is unconscionable, unfair, or confiscatory.

In case of merger or sale, to have the equity interest represented by his share protected. In the event of merger or sale of assets, the result commonly is a conversion of the shares of the merging company into shares of a new corporation or of the stronger of the combining concerns. In such case a shareholder is entitled to be offered securities in the new corporation representing equities in the new concern of approximately equal value to the equities held by him in the old concern. If he be a preferred stockholder he is entitled to a preferred position, and to have the amount of his preference in assets or dividends suitably recognized. If he be a common shareholder, he is entitled to the fair value of his equity in equity securities of the new corporation. This results in a battle of experts as to values; and one factor in this is the fairness with which information of values is given out to the shareholder to induce him to vote for or against the proposed merger or sale of assets.

To have the management act in the corporate interest only. Thus a management cannot, as individuals, purchase property which the corporation needs and resell it to the corporation at a profit. There is always the danger of becoming personally liable for any profit received. Again, the management cannot normally trade directly or indirectly with the corporation, though in many states if the result of the bargain is fair, the transaction will not be upset. Some states go to the length of upsetting any transaction where the management of a member of it has traded with its own corporation.

The foregoing summarizes the more important stockholders' rights. In individual application a management may run into singular and perplexing situations. Thus if the management is about to issue stock purchase war-

rants, the shareholder has a right that these shall be so handled as to yield the greatest amount of capital to the corporation. If the management is about to sell securities, the stockholder has a right that the management shall make the best arrangement reasonably possible with underwriters, etc. In like manner the stockholder is considered entitled to receive information from the management from time to time though this right is hazy. Corporations having their shares listed on the New York Stock Exchange are commonly obliged by the Exchange to publish periodic statements, in the form of balance sheets and income accounts, both for the guidance of the market and of their shareholders.

Certain specific rights are accorded to the shareholders by statute. Notable among these are:

The right to secure a stockholders' list. Any shareholder can normally demand that the corporation turn over to him its list, and penalties are provided where the list is refused. In New York there is an exception. Where the stockholder has used this procedure to obtain a list and then has sold the list for advertising or other purposes, his request may be denied.

The right to inspection of the books. On application to a court the stockholder can, on the showing of a legitimate interest or reason therefor, have an inspection of the account books of the corporation, and may put auditors on the books to accomplish such inspection.

The right to disclosure where the management is itself buying or selling stock. This is not true in New York or in a number of other states; but there is a substantial minority of states in which a director or officer of a corporation may not buy or sell stock from or to a shareholder without disclosing any unpublished facts which he may know affecting the value of the stock.

The right not to have dividends paid except out of surplus. States do not normally permit a corporation to pay dividends except where its assets are greater than all its liabilities, including as a liability the amount of capital set up behind its capital stock. This right has, however, been partly defeated by legal devices permitting creation of "capital" or "paid in" surplus carved out of the original consideration for the shares. Likewise, a corporation cannot purchase its own stock except out of surplus funds.

The right not to have the corporation speculate in its own stock. While the corporation is legally empowered to buy and sell its own stock in the market, it is probably not legal for a corporation to gamble or speculate in its own stock. Under appropriate disclosure, a limited amount of operation in support of the market may sometimes be permitted. By statute also in New York it is a penal offence for a director to sell stock of his corporation "short." This statute is so difficult to enforce, however, that it is, in practice, a dead letter.

All of the foregoing are merely more or less technical applications of the general rule that a corporation and its management have certain powers, which powers must be used in trust for the benefit of the whole. Where the fundamental right of a stockholder is violated, on appropriate application to a court he can obtain relief. A management can defend the action usually only by showing that the action taken was necessary to prevent misfortune befalling the corporation and its shareholders.

As between each other, stockholders have substantially no rights. There is one exception to this. Where one stockholder holds a controlling interest in the corporation and so dominates the management that he is virtually identified with it, stockholders are entitled to treat him rather as a member of the management than as a shareholder. But as between themselves shareholders are not bound to consider the interests of others; they may vote their stock for purely private reasons; they may trade against each other in the market; and the law recognizes no relation between them.

Stockholders' Duties. The obligations of a stockholder are hazy in the extreme, with one exception. Every shareholder must, on original issue of stock, subscribe and pay an equitable contribution, not less than par, if the stock have par value. Failure to live up to this obligation in general permits a creditor of the corporation to sue the shareholder in the event that the company becomes insolvent and requires him to pay up the balance of the par value (if the shares have par value). If the shares have no par value, probably the creditor has no such right; but another shareholder may sue either to impose a liability on the subscriber who has bought at a low price or to have the number of his shares cut down, or for other equitable relief.

Beyond that, shareholders are not considered as having any relation to each other. They are in no sense considered partners. While a majority of shareholders may not use their power to vote changes in the certificate of incorporation amounting to a confiscation of the property of the minority, this is regarded as an act of the corporation and not of the shareholders individually. Nor is a shareholder under any duty to disclose his knowledge when he trades in the stock of the corporation. He may enter a business which competes with the corporation. In this respect the old law that stockholders were in some sense partners has completely disappeared. A shareholder is not obliged to attend annual meetings; he does not have to vote; he may remain completely inactive throughout. If, however, he desires to object to any action of the corporation he must do so within a reasonable time after he knows or ought to know of it; and if he accepts any benefit from the action of the corporation he is estopped from subsequently attacking such action. Thus, if a stock dividend is declared and he accepts the dividend, he cannot subsequently attack the legality of that dividend because he has acquiesced in it.

The Unsolved Position of the Stockholder. The foregoing résumé indicates that the development of the law relative to shareholders has been unsatisfactory in the extreme. On the one hand in an attempt to protect him the law has worked out a series of more or less arbitrary rules which frequently prevent the management from acting with the necessary speed, or from taking perfectly legitimate corporate action. On the other hand, the economic disparity between the management and the shareholder has placed the shareholder in an extremely weak position. Finally, the entire mechanism of the corporation is at variance with the whole theory which the law has built up.

In earlier times investments were conditioned by the need of the investor; and stipulation was made to repay them at the time that the investor thought he would need his funds. This is no longer true today, largely because modern

business does not permit the withdrawal of capital at will. You cannot liquidate a plant; capital once locked up in it remains so for an indefinite period. Nor are corporations dissolved with any frequency; any theory that the investor's interest in assets on dissolution amounts to very much has been abandoned by bankers and economists alike. What the stockholder has got is a "*rente perpetuel*" or permanent right to participate in profits; and almost the only way he can get his money back is by a sale in the open market. As industrial property comes more and more under the corporate system, this throws the entire appraisal of industrial property into the speculative operations of the exchanges.

We have thus the paradoxical situation that the most serious business enterprises, and a great part of our national wealth, is valued from day to day not as a result of any intrinsic merit, nor even on the basis of the business situation, but often on the results of speculative operations, undue optimism or undue pessimism as the case may be. The shareholder claims ownership, but he assumes absolutely no responsibility; the management assumes responsibility but has not any well defined right to a share in the profits.

Control, Investment and Private Property. Concentration of power is bringing industrial property under a system which rivals in intensity the feudal system of the Middle Ages, or perhaps, the Communist system in Russia. At present, some 200 large corporations with less than 2,000 directors, actively control perhaps 30 per cent of the industrial wealth of the country; and they do so under a set of statutory and charter powers which permit them to sacrifice individual rights of shareholders to economic exigencies. It may fairly be said that private property under the corporate system has ceased to exist, at least in the sense in which it was known in the agricultural times of the last century. In its place has been substituted a series of expectations that the extremely limited group of corporate managers will deal fairly with the participants' tremendous blocks of property and the income streams which they are able to dominate.

Methods of domination have grown up which require relatively little investment or risk by the management themselves. In part this is due to the fact that industrial enterprises are of such size that no single individual or even group of individuals can make an investment large enough seriously to affect the situation. In part it is due to the development of devices by which a small block of voting stock controls a large corporation, which, in turn, uses its assets to buy the working control of other corporations, which, in turn, control still other corporations, thereby making possible a pyramid structure like that by which the Van Sweringens control a transcontinental railway system; the Eaton interests control a group of steel companies, and by which, at one time, Goldman Sachs & Company controlled a tremendous chain of more or less affiliated enterprises. It must not be implied that this power is necessarily abused: in the majority of instances the power is probably regarded as a public trust and dealt with accordingly. But it is used without reference to the shareholder, a frequent motive being often individual desire for power. Of all this the legal outline of the shareholders' position conveys very little.

It is obvious that we have by no means reached the end of this tendency. Concentration in the depression of 1929 to 1930 continued even more vigor-

ously than during the upswing from 1925 to 1929. As the number of shareholders multiplies their individual weakness grows greater; when their aggregate investment tends to grow continuously larger.

Liquidity of Investment and Market Operations. The shareholder needs protection in liquidity of investment. He should be entitled (though no method has been worked out or is yet in sight) to a market situation in which he can realize a reasonably fair value on his investment when it becomes necessary for him to withdraw his funds. To supply this liquidity, corporations list their shares on the stock exchanges; but the fate of exchange values is, as has been noted, largely in the hands of blind forces. That shares will fluctuate with the business cycle and with business conditions generally must always be true. It does not follow, however, that these inevitable fluctuations should be accentuated to an unbelievable degree of violence through irresponsible outside operations. It should be unthinkable that the corporation itself and the management which theoretically represents the shareholders, should at any time have an interest in the market adverse to the very shareholders who have supplied the capital. Yet all of these circumstances have been present at various times in the open market situation.

The Management as Professional Trustees. Leaving legal theory aside, shareholders' property under the corporate system is subject to a degree of control unheard of in previous modern history; the corporate management through its intrinsic powers, and through the power which it has to manipulate information and to enter the market, is in a position to deprive the shareholder of his property in a manner not accorded even to absolute governments for many centuries. It is a tribute to American business that this power has not been exercised to the detriment of the shareholder in the vast majority of instances. But the steady increase of the power indicates that a generation hence the problem will become of supreme importance. Put concisely, power over property has concentrated and will further concentrate in so few hands that there will be substantially an economic oligarchy, rivaling political government in actual power. This may very well be the best possible organization of industry; certainly, no better method of managing industrial enterprises has yet appeared. It does mean, however, that management must become increasingly professionalized; that its rights as against stockholders must be more clearly defined, particularly with reference to the share it is entitled to receive out of profits, and as to the degree to which personal considerations may be allowed to affect its actions.

Some commentators, notably Prof. W. Z. Ripley of Harvard, urge that the shareholders should be given greater voting rights. But there seems no reason to believe that a shareholder either can or will use these intelligently; the fact being that he rarely uses them at all, except in time of crisis and then only at the dictation of a group seeking to oust or control the existing corporate management.

The real development in this field would seem to lie in defining standards of accountability of management to shareholders. These turn, as nearly as can be estimated, on the following considerations:

1. *An increasingly professionalized attitude of business men.* As the managements of corporations become increasingly professional, acting under stand-

ards of ethics analogous to doctors, lawyers, or other professional men, they more nearly meet the role marked out for them.

2. *Increasing fullness and accuracy in recording and publishing facts as to the corporate operations.* In substance this comes down to accurate and ethical accounting. A difficulty arises here because accountants themselves are not agreed on standard methods of accounting, nor, (save in general lines) as to the ethics of accountancy. In general, the accountant is relied on to state the facts as to corporate values and corporate activities. The public is dependent on him both for information as to what the corporation has done and for the raw material from which an appraisal of corporate shares must be made. Thus the accountant has become one of the dominating forces in the stock market. If his accounting be legitimate, he is a healthy force. But until standardized methods of accounting are worked out and agreed on, and accountants insist on uniformity of accounting, there is a long road to travel before this type of accountability can reach its greatest effectiveness. The New York Stock Exchange is now pushing for standardized, clarified accounting systems.

3. *The shareholder must be educated so as to know the problems which the management must meet, the standards to which they are obliged to conform, and the meaning of the corporate steps taken.* In this respect managements have not begun to do what is fairly open to them. In part this is due to the desire of some managements to conceal the real reasons for the steps they take; but for the most part corporate managements simply have not gone to the trouble of educating their stockholders. Yet it would seem that an intelligent management, regarding its stockholders' list as a prime source of capital, and possibly as a market for its products, should indicate from time to time the precise significance of the major business steps taken; the reasons for accomplishing them by the particular means adopted; and the significance which the required legal steps really have. On this theory the stockholders' goodwill can be built up; the management is legally safer because it has disclosed the entire situation and therefore forecloses objection to the action taken; and, in the long run, has given stockholders a fair picture of its designs. Careful lawyers encourage this; and students of the situation insist on it as an ultimate necessity, though their views have only begun to penetrate the business world so far.

4. *Appropriate arrangements for compensation of management must be worked out and must be generally known to all interested parties.* Managements ought not to be required to resort to side operations, stock market campaigns, dilution of stock or the like, to receive substantial compensation for their services. Nor should shareholders be put in the position of having their interests in jeopardy from such devices. A defined arrangement can be made, so that profits are shared, a management receiving reward for successful labors. Arrangements whereby the management has to assume a position adverse to the shareholders to receive compensation are both legally and financially unsound. Open and well-understood agreements on the subject are possible which are both sound and safe.

Responsibility goes with power under any system, either of law or government. The broader the understanding of the subjects of the power, the safer

are those who exercise it. Much of the distrust of corporate managements arises from involved legal procedure (which no one bothers to explain) and from failure to recognize a duty to account comparable to the duty of a trustee. This is a business rather than a legal question, since courts cannot undertake to run businesses; legislative action is as likely to be harmful as helpful; and modern enterprises cannot be expected to abide by an arbitrary set of rules. The New York Stock Exchange has taken the initiative in requiring information and setting up certain rules of policy to safeguard shareholders. But in the last analysis this responsibility rests, not on the Exchanges but on corporations themselves, acting through their managements and their control. The alternative is government control,—a dangerous expedient at best, save in specialized forms of activity such as banking, and public utilities.

In summary, the position of a shareholder is that of a holder of a set of legal rights, many of which he cannot enforce, based on the general theory that he is entitled to have the corporate enterprise run for him as his interest may appear. In practice, legal rights cannot be enforced and the shareholder must rely on the good faith of the management as to the fate of his investment. As to withdrawal of his investment he must rely on the market, which at present is apt to be largely arbitrary in its appraisals. Meanwhile, the stockholder is coming to represent the vested property holder of the country; and he is coming to regard his management more in the nature of a government than in the nature of a business representative. Individually he is powerless; collectively, he can only act by a process almost as unintelligent as that of revolution, that is, his collective action is no better than the leadership which happens to supply itself in time of crisis. The management, on the other hand, knows very well that it has duties, not merely to the shareholder, but also to the public which it serves and to the community as a whole. It is obliged to balance these interests, and often to deal with business situations often of extreme difficulty, even though the result may be unhappy for its own shareholders. This responsibility it cannot avoid. The next decade will probably see a steady clarification of this situation through the increasing professionalism of the management, the increasing exactness in methods of recording and giving publicity to corporate activity, and in the increasing education of shareholders.

CHAPTER IV

BOARDS OF DIRECTORS, BOARD COMMITTEES, AND OFFICERS

FUNCTIONS OF BOARDS OF DIRECTORS, BOARD COMMITTEES, AND OFFICERS

BY JAMES O. MCKINSEY, *Senior Partner, James O. McKinsey and Company; Professor of Business Administration, University of Chicago*

Difficulties of the Subject. For several reasons this subject is a difficult one to discuss:

1. *There is little or no discussion of this subject in the literature of business management.* There is a considerable amount of discussion of the legal responsibility of boards of directors and officers of boards in the legal literature, but this does not discuss the responsibility which the board or its officers should assume in order to provide for efficient management.

2. *It is quite difficult to ascertain what authority and responsibility the boards and officers of boards of corporations exercise.* The only source of information available is the minutes of the meetings of the boards of directors and these do not give an adequate picture of the activities of the board. Many significant problems come before a typical board which are not recorded in the minutes. For example, the board of directors may discuss important problems with reference to executive personnel and with reference to the relationship of the company to competitors which they do not desire to have recorded in the minutes. There are many other questions of a similar nature which it is usually regarded inexpedient to have recorded in the minutes. There are also other questions which are not regarded of sufficient importance to be made a matter of record which are, nevertheless, significant in considering the activities of the board of directors and its committees. As a consequence even though we were able to examine the minutes of numerous corporations, we should still lack a complete picture of their activities.

3. *The activities of boards of directors and officers of boards in different companies vary so widely* because of the differences in the size of corporations and differences in their activities that it is hard to make generalizations.

4. *It is difficult to draw conclusions concerning the activities of different boards because we have no definite standards to use as a method of judging the efficiency of different boards.* We do not definitely know whether the practices of one board are better than those of another board although we may personally prefer the methods of one to those of another.

Conditions Determining Functions. The functions of boards of directors, vary from company to company. What a board of directors should do depends upon:

1. The nature of the activities of the business.
2. The size of the business.
3. Whether the board of directors is composed entirely of executives of the company or partly of executives and partly of members who are not employees of the company.
4. The financial condition of the business. If the business is prosperous the board of directors is very likely not to exercise as close supervision over its activities as if the company is in difficulties.
5. To some degree upon the financial structure of the corporation. If the stock of the corporation is held primarily by the executives of the company who are also the directors, the attitude of the board toward the management of the company may be somewhat different than if the stock is widely distributed and the board of directors is acting in more or less of a fiduciary capacity.

There are certain conditions which have tended to cause the board of directors to exercise more responsibility in the management of the business than they formerly did. There is a tendency for the managing group to be distinct from the ownership group. In the early development of corporations in the United States in most cases the executives were the principal owners of the business. During recent years stocks have been distributed more widely and in many cases the executives and even the directors of the group do not own the majority of the stock in the corporation. This has brought about the situation in which the board of directors acts in a fiduciary capacity. If they fully realize their responsibility, this naturally leads them to exercise closer supervision over the activities of the business than if they were not representing a large group who were not familiar with the activities of the business and who were not exercising any responsibility for the management of the business other than selecting the directors to represent them.

6. Management problems have increased both in number and complexity during recent years. As a result it is no longer wise to have decisions with reference to these problems made by chief executives alone or even by the chief executive and his major assistants. It is desirable that the executives have the benefit of the advice and judgment of a large group.

Functions of the Board of Directors. As a basis for discussion the functions of a board of directors may be summarized as follows:

1. It should be responsible for establishing the general objectives of the business.
2. It should establish the major policies of the business.
3. It should determine the organization structure of the business and select the major executives of this organization.
4. It should be responsible for "checking up" on the executives of the business to whom the responsibility for its administration has been delegated.

Each of these major responsibilities of the board can be subdivided to any extent desired and various classifications of its responsibilities can be made, but all of the activities of a typical board can be satisfactorily classified under one of these headings. A brief discussion of each of these functions of the board may serve to indicate its responsibility more clearly.

Relation of the Board to General Objectives. The board should determine the lines of activity in which the business is to engage. It should decide, for example, the number of lines of product it is to handle and whether it should manufacture or purchase the products it sells. It should decide whether it should enter the retail field in the distribution of its products or should distribute through jobbers or other means. It should determine the volume of its activities and the rapidity of growth which it should seek. It should decide with reference to its contact with other organizations both competitive and otherwise. It should decide whether it should produce and sell locally or nationally. In other words, it should determine what the general goals or objectives of the business should be.

Relation of the Board to Policies. After these general objectives have been determined, it should adopt policies which should establish the plan of action by which these objectives are to be attained. In a typical business the policies which must be adopted are numerous. The question immediately arises, therefore, as to what policies should be submitted to the board and what policies should be left to the judgment of the executives. It is obvious that the Board cannot pass on all the policies of the business. Any policies which may materially affect the prosperity of the business should be submitted to the board for its consideration. This statement is not a definite one and this plan leaves to the judgment of the executives to a considerable degree whether a policy is of sufficient importance to be brought to the attention of the board. This condition cannot be eliminated for after all we trust to a considerable degree the judgment of the executives of a business. If we eliminate the privilege of exercising this judgment, the executives cannot function efficiently.

One of the responsibilities of the board is to decide whether the executives exercise this judgment wisely. If the board of directors find by experience that the executives do not submit to it policies which it desires brought to its attention, it is then proper for it to give the executives instructions concerning their future actions. If the executives are not capable of carrying out such instructions wisely, then it is the privilege and responsibility of the board to secure other executives.

The wise executive will submit to the board for consideration all policies which he thinks are of significance to the prosperity of the company. In case of doubt as to whether the policy should be submitted, the wise executive will submit it to the board or a committee of the board. By following this plan, he protects himself. If the board approves the policy recommended by the executive and the results are not satisfactory, the board must share the responsibility for adopting the policy with the executive. We are all aware that in many cases it is impossible to secure so comprehensive information as we desire as a basis for making decisions. As long as this condition prevails, the executive should see that his board shares with him the responsibility of making important decisions.

Another important question is to what extent policies should be initiated by the board and to what extent they should be initiated by executives. This question cannot be answered arbitrarily. Primarily, responsibility for the initiation of policies rests upon executives. They are in daily contact with

the activities of the business and should be the first to see the need for changes in policy. However, if the board is composed of the proper kind of members, important questions of policy will often be raised by them. Members of the board should be encouraged to offer suggestions and information should be brought to their attention which will serve to stimulate their thinking concerning the policies of the business. The proper kind of board will often anticipate problems which would be overlooked by the executives.

The relationship between the executives and the board should be one of mutual cooperation in which the parties on each side are encouraged to give full play to their initiative. It is very important that an attitude be developed in an organization which will stimulate the offering of suggestions on the part of all members of the organization. Major executives should encourage their subordinates to offer suggestions and should give full credit to those who offer useful ones. Many times men who hold subordinate positions may have useful ideas concerning the management of the business which may not have occurred to the major executives or members of the board. We should therefore provide a means by which ideas and suggestions may flow freely from the bottom to the top of the organization and vice versa.

Relation of the Board to Organization Problems. After the general policies or plans of action of the business have been determined serious thought should be given to the type of organization to be used in executing these policies. The board should accept the responsibility of determining the type of organization to be employed by the company. In other words, it should determine to what extent the company should have a functional organization, territorial organization, commodity organization, etc. In most cases it will be necessary for the executives to offer suggestions to the board with reference to the type of organization to be employed. Where the executives fail to take the initiative in doing this, the board ought to take the lead in considering this problem. The board should have submitted to it at regular intervals a picture of what the organization is and what changes are contemplated in its development. It is accepted practice to submit to the board a picture of the financial condition of the business and more and more it is becoming customary to submit to it a budget showing the plans of the organization and the anticipated results of these plans. It is equally important that the board should have presented to it a picture of the organization and personnel of the business and the contemplated plans for its improvement.

After the organization of the company is established, the board should then select the major executives of the organization. They usually exercise this function by accepting or rejecting the recommendations of the chief executive. It is obvious that the board cannot pass upon all of the employees or even upon all of the executives of the business in the case of a large organization. The board should approve the selection of all the executives who report to the chief executive. The reason for this suggestion is that the selection of an executive should not be left entirely to the judgment of one individual and if the Board does not approve the selection of all executives who report to the chief executive, the selection of these executives will be left to the judgment of the chief executive. Therefore, the board should

approve the selection of such executives as the sales manager, the production manager, the treasurer, the comptroller, etc.

With reference to the executives who are subordinate to the major executives, the board may leave their selection to the chief executive and the immediate superior of the executive to be selected. For example, the assistant sales manager may be selected by the sales manager with the approval of the president. In this case, at least the judgment of two executives is required in the selection of an employee. In special cases in which the board may have reason to question the efficiency of a particular department, it may interest itself in the selection of executives below the rank of those mentioned but in general it is wise for the board to delegate as much authority and responsibility as possible with reference to these matters to the major executives so long as they have no reason to doubt their efficiency.

Responsibility of the Board for Checking Efficiency of Organization. If the board is to exercise proper control over executives to whom authority is delegated, it is necessary to have some means of checking their activities. The most customary way of doing this is by means of periodical reports submitted to the board. In many cases, however, these reports are only condensed financial statements and do not give the board sufficient information to enable it to judge the efficiency of the various executives. The board should have reports which will at least enable it to judge the efficiency of each of the executives whose selection it has approved. It is true, of course, that it is sometimes difficult to prepare statements which will correctly show the efficiency of some executives, but it is certainly possible to prepare much more comprehensive reports than those received by most boards. In addition to these financial statements, the board should receive at regular intervals budgets showing the program of each of the major executives as well as the program of the company as a whole. At the end of each accounting period it should receive statements showing a comparison between the budget for each period and the actual results. It is preferable that this budget comparison become a part of the regular financial reports so that it will not be necessary for the board to consider two sets of reports.

In addition to the information which the members of the board obtain from such reports it is desirable that they obtain some information by personal observation. Members of the board who are executives of the company will necessarily have a very considerable amount of information concerning what the executives of the company are doing and will be able to judge to some extent their efficiency. It is desirable that the members of the board who are not executives should also become acquainted with all of the important activities of the company by personal observation. To make this possible, it is necessary that opportunity be provided for the members of the board to inspect the activities of the business from time to time and to visit with the executives of the company who are not members of the board. Such a practice is not only beneficial to the members of the board but produces a desirable psychological effect on the members of the organization.

Composition of the Board. The functions which the board of directors should perform depend to some degree upon whether the board is composed entirely of executives in the business or whether some members of the board

are drawn from other lines of activity. There is considerable difference of opinion regarding this question. It is my opinion that the board should be composed partly of the executives of the company and partly of those of executive rank who are not employed by this particular company. In other words, it is quite desirable to have on the board of directors those who have been drawn from other lines of activity.

It is sometimes urged as an objection to this plan that it is difficult to secure executives from other lines of business who will give sufficient time and attention to the affairs of the companies on whose boards they serve to be able to give constructive advice and criticism. One has to admit that there are some who accept positions on boards of directors merely because of the honor attached to the position and who do not render worthwhile service to the company which they are supposed to serve. It is possible, however, to secure men to serve on boards of directors who will take a sincere interest in the affairs of the corporation. This plan is beneficial not only to the company on whose boards these men serve but also to the company by whom they are employed since it broadens their point of view. It should be valuable to have on the board men who have a wider experience than the executives can possibly have and who can consider the problems of the business from an outside and impartial point of view.

Functions of Committees of the Board. The second question we have for consideration is the functions of committees of boards of directors. The first question which naturally arises is why there should be such committees. The primary reason why we should have such committees is that boards of directors are taking their responsibilities more seriously and are taking a more active part in the management of the business. In order to do this, it is desirable that there should be committees to whom problems can be referred for careful consideration before the board attempts to decide with reference to those problems. If the board is to function in the manner suggested, it will be quite difficult for the board as a whole to give sufficient consideration to each problem brought before it to be able to arrive at a satisfactory solution. It promotes efficiency to refer many of these problems to committees which after careful consideration will make a report on them to the board.

The second reason for having committees is that many questions may arise during the intervals between board meetings which cannot wait for decision until the next meeting. It is possible to refer these to a committee which can act for the board during this intermission.

It is impossible to state arbitrarily the number of committees which any particular board of directors should appoint since the number depends upon the size of the business and the nature of its activities. In the typical corporation there should be at least one committee usually called the executive committee or finance committee which is authorized to act for the board with reference to problems of a general nature which need decision during the intervals between board meetings. In many corporations that is the only committee which is necessary. In some lines of activities there are other committees which are useful. For example, in a bank there may be the following committees:

1. The *finance committee*, which handles the problems already mentioned and in addition has jurisdiction over the making of loans. This committee is sometimes called the loan and discount committee.

2. The *advertising and new business committee*, which may control the expenditures for advertising and formulate plans for securing new business for the bank.

3. An *auditing committee*, which is responsible for supervising the records of the bank, inspecting the securities and employing professional auditors when this is deemed necessary.

In addition to the standing committees, special committees may be appointed from time to time to consider special problems which come before the board. Each of these committees should have a chairman and a secretary appointed by the presiding officer of the board. They should be required to keep minutes of their meetings and to make reports to the board at each meeting. It is not possible to state definitely who should be members of these committees. The chairman of a board should use his judgment in selecting those members of the board who are most competent to serve on each committee. Where there are sufficient committees to make it possible, some benefit is obtained from having all members of the board on some committee so that each member will feel that he has some definite responsibility to perform. These committees can be used as a means of stimulating the interest of the members of the board in the company. Of course, if too many committees are appointed and they are required to meet too frequently, they will fail to function efficiently and their operation will become burdensome.

The *kinds of questions which should be referred to such committees* fall into three general classes:

1. General questions which need to be considered during the interval between board meetings.

2. Problems which need to be given careful study before a solution is reached.

3. Special problems which arise from time to time and for which no precedent has been established and which, therefore, should be given special consideration.

In so far as is possible, the board should establish general policies which should control the actions of its committees. The committee's function is to apply the general policies to concrete cases. For example, in the case of a bank, the board of directors may adopt general policies regarding the type of loans to be made and the requirements for each kind of loan. It is necessary, however, to give consideration to the application of these policies to each concrete case and to make this application is the function of the loan and discount committee.

Officers of the Board. The officers of the board vary in number and responsibility according to the size of the company and the nature of its activities. The typical officers are chairman of the board, president, secretary, treasurer, and one or more vice presidents.

In some cases the president of the company serves as chairman of the board, while in other cases the board selects some member other than the president to

serve as chairman. There seems to be an increasing tendency to have a chairman of the board who is not the president of the company. In such a case, the question immediately arises concerning the relationship of the chairman of the board to the president.

Relationship of Chairman to President. The chairman of the board may be appointed under widely differing conditions. Sometimes a president of a company is made chairman of the board when he either desires to retire or the company wishes him to retire from active management of the business. In some cases the position is merely a nominal one and the chairman of the board exercises little or no jurisdiction outside of presiding at the meetings of the board of directors. In such cases, the president performs the function of chief executive and in some cases even presides over the activities of the board. In other cases, the chairman of the board may not be an active officer of the company and may even be employed in some other line of business. In such cases, he may exercise some general supervision over the activities of the business and is considered the superior officer to the president although the latter is usually given a considerable amount of freedom in the management of the business. In some cases such a chairman of the board is appointed when the business is refinanced by investment bankers. This places a representative of the bankers on the board to represent them in the management of the business. In other cases, the chairman of the board devotes his entire time to the management of the business and cooperates with the president in the administrative work.

It is in such cases that the relationship of the chairman of the board to the president becomes most important. The chairman of the board should devote his time primarily to questions of policy or major questions of organization and personnel, delegating to the president the responsibility of executing the policies adopted and directing the organization. This division of responsibility is justified in many organizations. Students of management recognized long ago in studying production problems that there is a distinct difference between planning and operating. This same distinction can be applied to the job of the chief executive and the chairman of the board may well concentrate on planning, leaving to the chief executive the problem of operating. In my opinion the chief executives in many organizations have imposed upon them responsibilities which are too great for one executive to perform most efficiently. This division of responsibility tends to lessen the task of the president and also provides an opportunity for the chairman of the board to give more time to studying the policies and major problems of the business than it is usually possible for the president to give if he has to assume all the administrative responsibilities of the business.

Duties of President. It is quite difficult to make generalizations with reference to the duties of the president. Assuming that there is not a chairman of the board and that the president is the chief executive of the business, his primary responsibilities may be as follows:

1. Giving careful consideration to the policies of the business.
2. Giving attention to the type of organization which the business should have and the personnel of this organization. This would include giving attention to the training of this organization.

3. Fixing responsibility on the members of the organization for executing the policies of the business.

4. Checking up on the organization to see that these responsibilities are properly executed.

If the chief executive is to perform these tasks properly it is necessary to delegate authority and responsibility to a considerable degree to his subordinates. Many presidents make their tasks more difficult by trying to perform too many detailed activities.

One reason why executives have not delegated authority and responsibility to subordinates to a greater degree is that in many cases they have not had satisfactory means of exercising control over those to whom authority has been granted. By developing effective statistical and accounting control and by developing budgetary control, it is possible for executives to control the operations of their subordinates. Therefore, they may safely delegate larger authority and responsibility. By so doing, they have sufficient time to concentrate on the major problems of the business. It is obvious that if the chief executive is to delegate authority, he must also define the responsibility of his subordinates. It is desirable that he present to all members of the organization a clear picture of what the organization is. The most effective method of doing this is by means of organization charts and manuals. Despite the limitations of such devices, their advantages far outnumber their disadvantages.

The Secretary. The duties of the secretary of a corporation are fairly well standardized. It is his responsibility to keep minutes of the meetings of the stockholders and the board of directors, to send the formal notices required of all meetings and to sign, on behalf of the company, legal and other documents. He may, of course, be assigned other duties when his time so permits.

The Treasurer. The task of the treasurer is to cooperate with the chief executive in formulating financial policies and in supervising the daily activities of the company with reference to financial matters. In a large organization the treasurer should have jurisdiction over the following:

a. The formulation of the financial policies of the company. He should exercise this jurisdiction through the general budget committee, the financial budget committee, the finance committee, and the board of directors. All of these units of organization, however, will rely upon the judgment of the treasurer to the extent which he convinces them that he is worthy of reliance. The treasurer should interpret his responsibility with reference to financial policies very broadly. In other words, he is interested in the efficiency with which the capital of the company is used by all units of the organization. Before he grants additional capital to the various units of the company he should be convinced that this capital will be used profitably by these units.

b. He should be responsible for procuring the capital needed to meet the requirements of all units of the company.

Of course, this statement must not be interpreted too literally for a considerable part of the capital of most companies is obtained by means of securities and the securities are marketed through outside agencies. The day by day requirements of the company are usually met, however, by current borrowing

and the treasurer is responsible for these. In a large company it is desirable that he establish a loan department which will handle these activities.

c. The treasurer is responsible for the handling of cash receipts and for the making of cash disbursements.

This will usually make necessary the establishment of a cashier's department which will have jurisdiction over these activities. A division of the controller's department should be responsible for authorizing disbursements, but the cashier's division of the treasurer's department should be responsible for actually making the disbursements.

d. He should be responsible for the purchase and disposition of all property of the company.

This will include not only the purchase and sale of securities, but also the purchase and sale of real estate. Of course, the purchase and sale of equipment and supplies is a function of the purchasing department. One may doubt the advisability of having the treasurer in control of the buying and selling of real property. He should be given this authority because the investment of the resources of the company in real property and the realization of these properties when they are no longer needed for the use of the company is entirely a financial problem. In other words, when the operating departments agree that they no longer need property which they have used it is the function of the treasurer to obtain from this property the greatest amount of capital possible.

e. In a large company it is profitable for the company to handle the transfer of its stocks and to pay its own dividends. In this case there should be established a transfer division which should be under the jurisdiction of the treasurer.

f. Credits and collections should be under the jurisdiction of the treasurer and consequently the credits and collections department should be a subdivision of the treasurer's office.

To summarize, the treasurer's department may be divided into the following main groups:

- a. Loan division.
- b. Sale and purchase of property.
- c. Cashier's division.
- d. Credits and collections division.
- e. Transfer division.

In some cases there may be other activities which should be placed under the treasurer, but the organization suggested should be sufficient for the typical company.

No responsibility for accounting matters has been placed upon the treasurer. In some organizations the accounting department is under the jurisdiction of the treasurer, but this is undesirable for two reasons. First, the treasurer is usually not competent by training to administer properly the accounting department because he is thinking primarily in financial terms and a large part of the function of the accounting department is to collect and interpret data concerning operating activities which should not be expressed in financial terms. Second, one of the functions of the accounting department is to

serve as a check on the financial operations of the business and it cannot do this as effectively and impartially if it is under the jurisdiction of the treasurer as if it is under an independent executive.

TRENDS IN THE FUNCTIONS AND COMPOSITION OF BOARDS OF DIRECTORS

BY ERWIN H. SCHELL, *Professor of Business Management, Department of Business and Engineering Administration, Massachusetts Institute of Technology*

Foreword. This study was undertaken at the request of a group of manufacturers who as the result of replies to inquiries had received contradictory opinion relative to the trend of directorate organization and operation. Through the cooperation of W. J. Donald, managing director of the American Management Association, questionnaires were sent to a considerable number of concerns engaged in manufacturing. The study, therefore, does not include consideration of public utilities, banks, insurance companies or distributive corporations. The investigation further limited itself to matters of directorate organization, personnel, and remuneration. Legal aspects, though important, were excluded from the scope of the research.

Conclusions resulting from an analysis of the collected data are presented with reservations. Certain of the questions, particularly those relating to probable future trends, could be answered only subjectively, and such opinions do not represent the combined opinion of any given board. Furthermore, changes which have occurred in directorates during the past ten years have not been of a radical nature. Frequently variations were found to be so slight that their statistical significance is questionable.

In the light of these conditions, it has seemed desirable to present with some completeness the data which have been collected in order that a basis may be available for evaluating the extent of indicated trends, or for reinterpreting the data in the light of additional facts resulting from personal knowledge of the subject.

For such general conclusions as are presented in this paper I assume personal responsibility.

A preliminary survey suggested that certain characteristic differences might be anticipated between the directorates of larger and smaller concerns. The classification in terms of annual sales, of concerns answering the questionnaire follows:

	Number of Concerns
Sales less than \$100,000.....	0
\$100,000 to \$500,000.....	4
\$500,000 to \$1,000,000.....	9
\$1,000,000 to \$5,000,000.....	42
Sales over \$5,000,000.....	62

This tabulation indicated that \$5,000,000 would be a desirable point at which arbitrarily to draw a line between the larger and smaller concerns.

Such a demarcation showed further significance when considered in terms of numbers of employees:

Average number of employees	54 smaller concerns, per cent	62 larger concerns, per cent
Less than 200.....	19	0
200 to 500.....	46	3
500 to 1,000.....	28	8
1,000 to 5,000.....	7	53
Over 5,000.....	0	36

It shows that 93 per cent of the smaller businesses employed less than 1,000 persons, while 89 per cent of the larger businesses employed more than 1,000 persons.

The following classification of the holdings in these two groups of salaried officers who were active in the business was made:

Salaried officers	54 smaller concerns, per cent	59 larger concerns, per cent
Represent all of voting stock.....	18	8
Represent majority of voting stock....	56	36
Represent less than majority.....	15	39
Represent nominal amount only.....	11	17

Stock control in the smaller concerns was found to be to a considerably greater extent (75 per cent) in the hands of men who were active in the business than was the case in the larger businesses (44 per cent).

Figures giving the number of directors and average number per directorate follow:

	55 smaller concerns		62 larger concerns	
	1919	1928	1919	1928
Total number of directors.....	315	333	506	579
Average number per directorate.....	5.7	6.1	8.2	9.3

These reflect a trend during the past ten years toward an increased number of directors per board with a greater expansion occurring in the larger boards.

Opinions concerning the probable future size of boards were classified as follows:

Size of boards	49 smaller concerns, per cent	59 larger concerns, per cent
Will increase.....	27	17
Will decrease.....	12	15
Will show no change.....	61	68

A general satisfaction with the present situation is reflected, although slightly more of the smaller concerns look for an increase in size of boards than do larger concerns.

On the boards of the larger companies the percentage of outside directors (not actively employed in the business) to the total number of directors reported, increased from 34.6 to 36.9 per cent, while on the boards of the smaller concerns the same percentage for the ten-year period dropped from 40.1 to 37 per cent. Both large and small concerns now have, therefore, almost the same ratio.

The result of these changes in the size and composition of an average board is shown in the following table:

	55 smaller concerns, average number of directors		62 larger concerns, average number of directors	
	1919	1928	1919	1928
Directors actively connected with operation of business.....	3 4	3.9	5.4	5.9
Directors not otherwise active in business.....	2 3	2.2	2.8	3.4
Total number of directors (average)....	5.7	6.1	8.2	9.3

It is clear that the smaller establishments enlarge their boards through the appointment of active officials while the larger concerns are drawing upon both inside and outside talent when increasing their directorates.

To the question, Will the number of directors who are also operating executives with salary tend to increase or decrease? the summary of replies is as follows:

Number of operating directors	51 smaller concerns, per cent	59 larger concerns, per cent
Will increase.....	45	44
Will decrease.....	12	14
Will show no change.....	43	42

The table reflects a considerable satisfaction with present ratios, and an equally strong opinion that such operating directors will increase in numbers.

The following table classifies similar questions relating to directors drawn from the outside:

Number of outside directors	49 smaller concerns, per cent	56 larger concerns, per cent
Will increase.....	14	11
Will decrease.....	49	41
Will show no change.....	37	48

This indicates that such directors will not tend to increase in numbers in either group of concerns.

Changes in the principal occupations of directors are shown in the following table:

Principal occupations	55 smaller concerns, per cent		62 larger concerns, per cent	
	1919	1928	1919	1928
Presidents.....	12.1	11.4	9.7	8.6
Vice presidents.....	8.3	8.1	12.5	13.1
Secretaries.....	6.0	6.9	4.3	4.7
Treasurers.....	7.3	8.7	6.5	5.9
Sales managers.....	2.9	3.6	3.8	3.6
General managers.....	2.9	2.1	1.0	.5
Chief engineers.....	.3	1.2	.8	1.6
Other executives.....	7.6	12.0	15.6	14.5
Capitalists (usually retired).....	1.9	2.1	5.7	2.1
Attorneys.....	6.7	3.6	4.5	4.7
Business men (not in this business).....	17.1	15.6	9.9	11.4
Manufacturers.....	5.4	6.9	3.2	4.3
Bankers.....	4.8	3.0	8.1	10.2
Occupations not reported.....	16.8	14.7	14.4	14.8

In considering the smaller *vs.* the larger concerns, comparisons cannot be too finely drawn as terms were not sharply classified. A vice president, for example, may be a vice president and general manager or a vice president and treasurer, etc.

The smaller concerns are showing a tendency to reduce the numbers of attorneys and bankers who have been sitting on their boards. Such reductions are partly compensated for by increases in the appointment of non-competitive manufacturers.

The larger concerns have increasingly enlisted the counsel of bankers and outside business men, while the capitalist, who was usually a retired member of the business, is definitely withdrawing. There is indication that non-competitive manufacturers will be called into service as directors in both groups to a larger extent in the future, and outside business men will continue to occupy an important place on such directorates. The use of the vice presidential title appears to be in greater vogue in large concerns, and the inclusive nature of this term probably accounts for the decline in the incidence of general managers and treasurers during the past ten years. The increasing dissimilarity in the ratios of bankers in the two directorate groups is worthy of note.

A classification of the primary reasons given for presence of directors on boards is shown in the following table:

Reasons for presence on boards	55 smaller concerns, per cent		62 larger concerns, per cent	
	1919	1928	1919	1928
Knowledge of details of business.....	22.0	21.9	24.2	25.0
Sound executive judgment.....	14.0	15.4	13.4	16.7
Important stockholder.....	21.8	16.0	17.5	17.1
Represents important stockholdings.....	7.0	8.4	8.0	8.8
Represents financial interests.....	3.5	2.4	3.4	2.8
Financial counsel.....	5.3	5.4	4.9	4.7
Legal counsel.....	3.5	2.3	3.1	2.5
Knowledge of external business conditions....	7.3	9.8	9.7	8.8
Represents customers or brings business.....	7.2	7.1	5.0	3.7
Brings prestige.....	3.5	4.8	4.3	3.5
Represents allied manufacturing or commercial interests.....	.7	2.4	2.7	2.4
Represents employees.....	1.0	.8	.2	.5
Reward for services.....	3.3	3.3	3.5	3.5

It is evident that in the smaller concerns the percentage of directors who hold their place by virtue of their importance as stockholders, has declined and was, in 1928, about equal to that found in larger concerns. In this

smaller group where the stock control is usually in the hands of active officials the outside director must to an increasing extent prove his value by virtue of some definite service such as knowledge of external business conditions, ability to represent customers or bring business, increase prestige or coordinate allied commercial or manufacturing interests.

In the larger concerns knowledge of business details appears particularly valuable as does sound executive judgment and may account in part for the enlargement of such boards to accommodate a greater number of active officials, and it is interesting to note that those directors whose value has resulted in part from their external influence, *i.e.*, business bringers, prestige bringers, financial representatives, legal counsel, and allied manufacturing representatives, are finding such activities of lessening significance. This trend is, in the main, opposed to that found in the smaller concern. The lowering ratio of significance attached to the representation of financial interests and to financial counsel suggests that the increase in bankers on the larger boards is not due to these causes, but to their powers of business judgment, although they may, in some cases, be representing important stockholdings.

A tabulation of the nature of stockholdings of directors follows:

Stockholdings	276 directors in 55 smaller concerns, per cent		429 directors in 62 larger concerns, per cent	
	1919	1928	1919	1928
Large.....	49	44	48	45
Nominal.....	49	53	47	48
None.....	2	3	5	7

These data suggest policies on the part of both groups that provide new directors serving on enlarged boards with only nominal amounts of stock. While the percentage of large stockholders in both large and small concerns shows a decline over the ten-year period, the proportion of directors who have nominal stock interest or no interest is very slightly increased.

The following summary indicates requirements affecting the amount of stock owned by directors:

Requirements	55 smaller concerns, per cent	58 larger concerns, per cent
No voting stock required.....	24	24
Nominal amount.....	69	69
Substantial amount.....	7	7

This reflects the strong tendency in both groups toward nominal requirements, which frequently are in response to legal regulations.

The appointment of a director to the position of chairman of the board occurs in 28 per cent of the larger concerns and only 6 per cent of the smaller. In the remaining instances, the president performs such functions.

A summation of replies to the question, Will the position of chairman of the board increase or decrease in importance in the future? follows:

Importance of chairman of board	46 smaller concerns, per cent	54 larger concerns, per cent
Will increase.....	31	28
Will decrease.....	13	22
Will show no change.....	56	50

The table suggests that increased use of this office will take place but slowly.

Boards of larger companies also make greater use of executive or finance committees composed of directors, 45 per cent of such boards (forty-nine reporting) appointing an executive committee, while an additional 6 per cent appoint both executive and finance committees. The major reason for such committees was given to be the wide geographic dispersion of directors, although some committees were said to expedite business, or to capitalize intimate knowledge of operating problems, possessed by the members. Smaller concerns appointed executive committees from directors in 23 per cent of the forty-four plants reporting. In both groups, the use of executive or operating committees composed rather of salaried officers reporting to the president were found to be prevalent, 46 per cent of the larger concerns and 25 per cent of the smaller concerns making use of such committees.

The following table classifies opinion with respect to the future trend of executive committees composed of directors:

Use of executive committees	41 smaller concerns, per cent	49 larger concerns, per cent
Will increase.....	42	33
Will decrease.....	9	12
Will show no change.....	49	55

Responses from smaller concerns appear more favorable to development of such committees than do responses from larger concerns, where such com-

mittees are more widely in use. The largest number in each group, however, feel that no change in present status is to be looked for.

The frequency of meetings is shown in the following table:

Meetings	53 smaller concerns, per cent	59 larger concerns, per cent
Annual.....	13	3
Semi-annual.....	11	2
Quarterly.....	32	34
Monthly.....	38	53
Weekly.....	6	8

A tendency toward greater frequency of meetings among the larger concerns is reflected, which would indicate that such meetings are held to be more important by this group of establishments.

Responses to a question regarding the probable future frequency of directors' meetings follow:

Directors' meetings will be held	50 smaller concerns, per cent	58 larger concerns, per cent
More frequently.....	44	34
Less frequently.....	0	0
With no change in frequency.....	56	66

These suggest a considerable minority opinion in both groups that meetings should be more frequent, although the majority appear satisfied with present conditions. Small establishments appear somewhat more interested in greater frequency than do large, a condition which may tend to bring frequencies in the two groups nearer to a parity.

A tabulation of directors' fees is given herewith:

Directors' fees	55 smaller concerns, per cent	52 larger concerns, per cent
Paid to all directors.....	27	17
Paid to certain directors.....	16	39
Not paid.....	57	44

It shows that the larger concerns were more inclined to such payments. A grouping in terms of size of fees is necessarily fragmentary as many concerns did not report on this question:

Size of fees	18 smaller concerns, number	36 larger concerns, number
\$ 5.....	5	0
10.....	7	8
15.....	0	1
20.....	3	17
25.....	1	7
40.....	0	1
50.....	0	2
100.....	1	0
250.....	1	0

Data suggest \$10 as the characteristic fee paid by the smaller concerns, while \$20 is the one most frequently employed by the larger.

In three instances smaller companies are paying annual retainers to all directors of \$1,000, \$600, and \$100, respectively, while one large company reports paying to all directors a retainer of \$500.

Concerns paying such annual fees to certain (not all) directors are classified as follows:

Annual fee	3 smaller concerns, number	5 larger concerns, number
\$ 500	0	1
600	1	1
1,000	2	0
1,500	0	1
6,000	0	2

Such payments are relatively rare in the procedure of the companies reporting. In two additional instances annual payments were made to corporation counsel or to members of the executive committee, but amounts were not given.

Of both larger and smaller reporting concerns 80 per cent stated that directors as such did not share in the profits of the business. Of the remaining number, a portion gave specific data as follows:

	10 smaller concerns, number	11 larger concerns, number
All directors share in profits.....	2	6
Certain directors share in profits.....	8	5

The following table reflects a predominating opinion that directors' remuneration, further than the payment of dividends or directors' fees is not expected to increase in the future:

Other forms of profit sharing	45 smaller concerns, per cent	52 larger concerns, per cent
Will increase	20	13
Will decrease.....	2	6
Will show no change.....	78	81

This attitude is interesting in view of the rather general practice of directorate profit sharing in English and Continental boards.

There appeared to be a greater tendency among smaller companies to pay traveling expenses to directors (74 per cent of thirty-one concerns reporting) than among larger companies (57 per cent of fifty-three concerns reporting), a condition which may be affected by dissimilarities in frequency of meetings and size of directors' fees in these groups. Comments noted on the responses from smaller companies indicated that directors usually resided in the vicinity.

Summary. The directorates of the smaller concerns are relatively small in size and slow to expand with little evidence of desire in this direction. Such growth in size as has taken place has come through the addition of operating executives, while the number of outside directors has decreased slightly, and there is considerable opinion to the effect that any further changes should be in the direction of more inside and less outside directors.

Bankers and attorneys are appearing in lesser degree upon such boards, but their withdrawal is partly compensated for by increases in the numbers of outside manufacturers, while outside business men are continuing to hold an important place in such organizations.

Important stockholdings are a lessening justification for presence on these boards. If an inside executive, knowledge of details of business or sound business judgment is increasingly important, while the director not otherwise employed in the business must command a knowledge of external busi-

ness conditions, an ability to enhance sales through prestige or personal influence, or to effect cooperation with allied interests.

As such boards increase in size, a slight tendency is evidenced for new members to receive nominal stock interests. The appointment of chairman of the board, executive or finance committees, is infrequent in this group and there is little desire for change in these directions. While the most popular meeting period is a monthly one, over one-half of the meetings are held at quarterly or longer intervals but sentiment inclines toward shorter intervals in the event of any change. Less than half of these concerns pay directors' fees, the popular amount being \$10, and there is little evidence of the use or desirability of annual retainer fees or profit sharing for directors as such. Three-quarters of these concerns paid traveling expenses of directors when necessary.

One gains the impression that in these businesses where stock control is largely in the hands of operating officials, there is a growing conviction that directorates should remain small and self-inclusive except in such cases where the advantage of outside memberships can be definitely established. There appears to be a growing awareness, however, that such outside members contribute value which may not otherwise be procured. While the close relationships which exist between stockholders, directors, and operating executives in these businesses, render the administrative activities of the board somewhat less essential to the conduct of the business, there is definite indication that the pressure of business conditions is bringing about changes which are leading to the greater effectiveness of such bodies.

In the larger group of concerns having annual sales of \$5,000,000 or over, the average board is 50 per cent larger than in the smaller group and the trend of expansion is more rapid, increases occurring in both inside and outside members, to the point that about three out of every eight members are not otherwise actively concerned in the business. There is nevertheless considerable opinion to the effect that future changes, if any, will be in the direction of more inside men.

The last ten years have seen the withdrawal of the retired capitalist from such boards, and his place has been taken by the banker and outside business man, both of whom seem to be appointed because of sound business judgment rather than because of specialized skill, personal influence, or position as financial representatives.

The appointment of a director as chairman of the board has occurred in about one-fourth of these companies and the outlook is for a slow increase in this direction. The appointment of executive committees of the board, a practice which is much more prevalent here than in the smaller concerns, shows promise of further slow development. Although over one-half of the directors' meetings occur monthly or oftener, there is an evident desire for more frequent meetings. Directors' fees which are paid in more than half of the companies are popularly \$20 per meeting, while annual retainers or methods of profit sharing are very infrequent. In about one-third of the instances, traveling expenses of directors are paid.

Responses from these larger concerns lead one to believe that it is from these boards that the more significant developments may be anticipated.

During the past ten years the appointment of directors other than the president to the position of chairman and the use of executive committees are instances of definite steps which this group has taken in matters of organization, while the greater frequencies of meetings and higher directors' fees are indicative of the added importance which is attached to their functioning. The striking characteristic is the growing emphasis upon knowledge of business details and sound executive judgment. Whereas the smaller boards are tending to reject stock ownership alone as a sufficient basis for a directorship, large boards have gone a step further and indicated that not only the fact of ownership, but such personal qualifications as knowledge of external business conditions, business-getting ability, and the like, are to take second place before the urgent need of directors who excel in a knowledge of the business and its details and whose statements incorporate a dependable quality of business judgment.

THE FINANCE COMMITTEE

BY JAMES O. MCKINSEY, *Senior Partner, James O. McKinsey and Company; Professor of Business Administration, University of Chicago*

Reasons for the Establishment of the Finance Committee. There has been a distinct tendency during recent years for the boards of directors of corporations, even of moderate size, to take a more active part in the management of the corporations they represent. It has been found that the management problems of these corporations are so numerous and complex that it is not wise to leave decisions with reference to them to the judgment of the chief executive alone. The directors have come to realize that they are responsible to the stockholders for the management of the corporation and that as a consequence they are acting in a fiduciary capacity which places upon them the burden of exercising extraordinary diligence to see that the corporation is managed properly.

Because of this tendency on the part of the board of directors to accept more responsibilities, it has been found that numerous and complex problems are brought to them for consideration. In many cases it has been found impossible for the board, as a whole, to be sufficiently familiar with all of these problems to handle them in an effective manner. As a consequence the board has found it wise to appoint one or more committees which can study these problems in more detail and make recommendations to the board. It is also found that some problems arise between board meetings which require prompt action and it promotes efficiency to have a committee which can act for the board, promptly.

In some corporations there are appointed:

- a. An executive committee.
- b. A finance committee.

It has been found, however, that there is some difficulty in having these two committees function separately. Many of the problems which are referred to the executive committee involve questions of finance which need to be passed upon by the finance committee. In the same manner financial

problems which are referred to the finance committee often involve a consideration of other problems which rightly fall within the province of the executive committee. If there are two committees, delay is likely to result by referring these questions from one committee to the other. This difficulty may be overcome in two ways:

- a. By having these two committees hold a joint meeting when problems are to be considered which fall within the province of each committee.
- b. By combining the committees into one committee which is usually called the finance committee.

In a corporation of moderate size it is usually satisfactory to have one committee and we shall assume in the following discussion that there is only one committee.

Responsibilities of the Finance Committee. The usual responsibilities of the finance committee can be classified as follows:

1. *To Pass upon Major Questions of Policy.* It is impossible to state definitely the kind of questions of policy which should be referred to the finance committee. Generally, any question which is to be considered by the board should first be considered by the finance committee. The board or the finance committee can designate from time to time certain policies on which they wish to pass. With reference to other questions of policy which are not covered by specific instructions, the president or the chairman of the board must use his judgment. The number and kind of policy questions which will be referred to the committee depends to a very large degree upon the size of the corporation, the nature of its problems, the composition of the board of directors, and the ability of the chief executive.

In the case of a new corporation a large number of questions of policy will be referred to the board. After the policies of the company have been established, it will only be necessary to refer to the board and the committee, important changes in these policies. If the chief executive and his associates prove their ability to decide questions of policy, the board will gradually grant them greater authority.

If the board is composed entirely of the executives who are employed in the company, the president will discuss many of these questions with these executives in an informal way which makes it unnecessary for them to be passed upon by the board.

If the board is composed partly of stockholders who are employed in other lines of activity, the wise chief executive will refer all major questions of policy to the board so that he may obtain the benefit of the advice of those members of the board who have an outside point of view.

2. *To Pass on Major Changes in Organization or Major Changes in Personnel.* Students of management have learned in recent years that the form of organization of a corporation is very important and as a consequence boards of directors take more interest in organization problems than in previous years. It is customary, therefore, for the chief executive to secure the approval of the board of directors on major changes in the organization structure of the corporation.

For example, if the chief executive and his associates have decided that the corporation should cease to sell its products through jobbers and develop

a sales organization to sell direct to retailers, this change in organization structure and sales policy should be passed upon by the board and consequently by the finance committee.

If the chief executive decides that a personnel department should be established under the administration of a major executive, this change in policy and organization should be approved by the finance committee and the board of directors.

There is no established policy concerning the executive appointments which should be approved by the committee and the board. It is the opinion of the author that the president should secure the approval of the committee and the board to the appointment of all executives who report directly to the chief executive. By this means, there is a double check on each of these executives. If this is not done these appointments are subject only to the approval of the chief executive. For example, the chief executive should submit to the finance committee for approval the appointment of a sales manager. It is not essential that he submit for its approval the appointment of an assistant sales manager since this appointment would be subject to the approval of both the sales manager and the president which provides for a check on the judgment of the chief executive.

3. *To Pass on the Budgets of the Company.* The chief executive should submit to the finance committee prior to the beginning of each budget period budgets on income, expenses, investments, and finances. If these budgets are properly prepared they will bring in review to the board all the major policies of the corporation, for the budget if properly prepared should be a statement of policy.

For example, the sales budget, which is a major division of the budget on income, should present the sales policies which the sales department and the chief executive think should be followed.

If comprehensive budgets are submitted to the finance committee and if monthly comparisons between the budgeted performance and the actual performance are submitted to the committee for its consideration each month, it is enabled to exercise an effective control over all the activities of the business. Usually the committee reserves to itself the right to pass on major expenditures even though these are provided for in the budget.

It will be seen that if the program we have outlined for the finance committee is followed its functions may be summarized as follows:

- a. It passes on the policies of the company.
- b. It passes on the organization and personnel responsible for carrying out these policies.
- c. It passes on the program of these executives by means of the budget. As a consequence it is enabled to change the plans of these executives prior to their execution, if it so desires.
- d. It checks up on the efficiency of the executives by means of monthly reports which show a comparison between plans and accomplishments.

It will, of course, be understood that under special conditions other problems may come before the finance committee, for example, in cases of mergers or liquidation of companies, many special problems will need to be brought to the consideration of the finance committee. It is never possible to state

its responsibilities in detail and it is always necessary to leave these responsibilities in each specific case to some degree to the judgment of the committee and the chief executive of the company.

Composition of the Finance Committee. The finance committee should be composed entirely of directors of the corporation. The committee at its discretion may have executives of the company who are not directors confer with it. If the board of directors is composed partly of executives of the company and partly of stockholders who are not employed by the corporation, it is wise to have both types of directors represented on the finance committee. Whether the majority of the committee should be composed of executives or stockholders who are not executives depends to a considerable degree upon the special abilities of the members representing each group. In any case it is desirable to have both points of view represented on the committee.

There is no uniform practice with reference to who should be the finance committee chairman. In different corporations the following serve as chairman:

- a. Chairman of the board.
- b. President.
- c. Member of the board employed by the corporation for this particular position.
- d. Member of the board not in the employ of the corporation.

In the opinion of the author it is in most cases preferable to have the chairman of the board or the president serve as chairman of the finance committee. These executives are responsible for the management of the business and should be in a position to function most effectively as finance committee chairman.

If a third executive is employed for this position, there is a tendency to divide final responsibility for the management of the corporation. There are, of course, special conditions where it is desirable to have neither the chairman of the board nor the president, serve as finance committee chairman. For example, in the case of financial reorganizations, a representative of the financial interests which assume responsibility for the reorganization may serve in this capacity.

In other cases the chairman of the board may not be active in management of the business and the president may not be of the type who can function most effectively as chairman of the finance committee. In this event a third executive may appropriately be employed for this position.

Relation of the Finance Committee to the Executives of the Company.

The finance committee represents the authority of the board of directors and is, therefore, superior to any official of the corporation. As a consequence the president of the company and the chairman of the board are subject to its jurisdiction and should report to the board through it.

In some cases the treasurer and the controller report directly to the finance committee. It is contended that this is desirable because it gives the finance committee, as a representative of the board, direct control over the financial and accounting activities of the company and consequently a direct check on the activities of the operating executives of the company. In the author's opinion this plan is not desirable in most cases.

The board of directors acting through the finance committee should hold the chief executive of the company directly responsible for the management of the business. It is a fundamental principle of organization that authority and responsibility should go hand in hand. If the chief executive is to be held responsible for the management of the business he should also be given authority over all the activities which contribute to the success of the management. It seems proper, therefore, that all of the employees of the corporation should report through the chief executive to the finance committee and the board.

It is impossible in a brief discussion of this nature to deal with all the special conditions which may exist in some cases. The purpose of this discussion has been to outline the responsibilities and organization of the finance committee in a typical corporation operating under normal conditions.

THE COMPTROLLER

BY J. P. JORDAN, *Partner, Stevenson, Jordan, and Harrison*

Probably no official in industry or in commerce has so many varying scopes, duties, responsibilities and lack of responsibilities as the individual called the comptroller. He varies in scope and dignity all the way from the bookkeeper to almost the chief executive officer of the company. One of the principal uses of the title is to bestow it in place of a raise, and thereby it has become a very much misused and beclouded handle.

As a matter of fact, whether he is known as comptroller or by any other title, there is room in any and every organization for someone to fill the niche which we will discuss. By a process of evolution, we have come to believe that there are certain definite functions which make up the job called comptroller, mostly because of his connection with the statistical work which he supervises, but partly because there are a lot of odd little things which are thrown into his bag of troubles on account of there being no other place to put them.

It is quite readily conceded that the primary duties of the comptroller are in respect to the record procedures of the company, and that the corollary is the responsibility for office work in general, as most of it is concerned with record procedures anyway. The usual questions which come up, however, are as to the extent of the control held by the comptroller, both over records and office procedure, particularly in offices other than that of the comptroller himself.

In order to approach the discussion of this subject with something definite in mind, there is now given a quotation from the manual of a large company giving the duties of its comptroller:

Comptroller's Department

General Scope. The comptroller's department is responsible for all records and reports of every description throughout the company and its subsidiaries, from three very important angles:

1. From the standpoint of correct assembly of original data, the recording of same, and the compiling of proper statements and reports.

2. From the standpoint of the intelligent interpretation of all statements and reports.

3. From the standpoint of cooperation with all responsible officials and department heads to insure the fullest and most efficient use of the records for constructive betterment of all operations.

Included in the foregoing shall be the supervision of forecasting and budgeting in all departments of the company and its subsidiaries.

In addition to the matter of records, statements, and reports, the comptroller's department shall be responsible for all clerical and office methods and procedures throughout all departments of the company and its subsidiaries.

The comptroller's department shall have auditing powers of all receipts and disbursements and property of every description.

The carrying out of the responsibilities of the comptroller's department shall be accomplished by two methods:

1. By direct physical jurisdiction where such jurisdiction is indicated as best.

2. By functional jurisdiction where it may seem best that the actual performance of work should be under the physical jurisdiction of heads of departments other than the comptroller's, but where the methods and procedures used will be specified by the comptroller's department.

Title of head.....	Comptroller
Located at.....	Headquarters
Reports to.....	Chief executive

Responsibilities of Comptroller. The comptroller is responsible for maintaining an economical organization for the purpose of devising, installing and operating efficient methods of gathering data, assembling data, and preparing intelligent reports and statements of all operations of the company and its subsidiaries; and also, for the organized supervision of all office methods and procedures throughout all departments of the company and its subsidiaries.

An equal or more important responsibility of the comptroller is that of so cooperating with all the officials and department heads of the company and its subsidiaries that the entire organization will be constantly in possession of complete facts as to present and forecast future conditions, and of assisting all officials and department heads in every possible manner in their work of bettering previous results.

Specific duties of the comptroller include the following:

1. To supervise all subsidiary divisions of his department.
2. To constantly work to reduce the cost of all record and office work without curtailing the value of the accounts, records, and reports.
3. To keep fully informed as to all labor-saving devices for office work of all kinds and recommend same where savings may be made.
4. To supervise the standardization of all record procedure in all offices of the company and its subsidiaries.
5. To supervise the standardization of all methods and office procedures in all offices.
6. To provide for approval of all forms before adoption by any department of the company and its subsidiaries.
7. To provide for approval of all requisitions for printed matter.

8. To supervise the taking of all inventories of the company and its subsidiaries. In addition, the comptroller may, at his discretion, cause inventories or checks of stock records and inventories to be taken at any time.

9. To supervise the preparation of all tax reports of the company and its subsidiaries.

10. To supervise the preparation of all forecasts and budgets throughout the company and its subsidiaries.

11. To maintain, either personally or through qualified assistants, a constant touch and cooperative relation with all responsible officials and department heads whereby the operations of the company may be constantly improved.

12. To interpret, when necessary, by a brief guiding résumé or otherwise, all statements and reports whereby executives and department heads may proceed without being obliged to study many detailed figures in order to ascertain points needing attention. This will require study on the part of the comptroller or a qualified assistant of all statements and reports before they are released by his office.

13. To interpret more effectively the course of results, the comptroller shall supervise the preparation of such special statistics as are required; and shall cause to be prepared such graphic and other presentations as shall strikingly and effectively present a comprehensive picture of pertinent facts and trends.

14. To include among other auditing operations a specific audit and study of all personal expense accounts of every description with recommendations in connection therewith.

15. To make any special investigation of any matter at the request of the board of directors, the chairman, or the president.

16. To examine and endorse upon each proposed expenditure for additions to capital accounts an opinion as to their earning value to the company and its subsidiaries. In like manner, the comptroller shall examine and report upon all proposed expenditures for repairs or replacements above a figure fixed by the management or in accordance with any policy which may be established.

17. To provide close checks on the progress of expenditures, purchases, or other commitments against all capital additions and specially approved repair or replacement items, in order that such items may be properly controlled. In performing this duty, the comptroller may, as he deems necessary, enlist engineering aid in appraising the progress of work in order that a proper control may be assured.

In reviewing the duties of a comptroller as just described, it is obvious that the setting up of such duties and the scope thereof must be fitted to the size and nature of each company. There never was and never will be any such thing as a standard definition of the scope of *any* official function in any company. Every company differs. But there are such things as rather fundamental principles, and it is with those that we may well concern ourselves, for if we do, each one can then analyze for himself the conditions of his own business, whether it be large or small, and can apply these fundamentals to the circumstances which may be found to exist; and therefrom construct a very satisfactory set-up of duties for the particular comptroller.

Interpretation of Statements. How many men holding the title of comptroller purely and simply from the standpoint of bookkeeping experience can qualify on the interpretation of statements? The day of saying "Well,

that's what the figures turned in say" has long since gone by. The comptroller's department must know enough of the operations, the figure results of which are being recorded and presented, to determine what the figures mean and to be able to interpret them in language which is the language clearly understood by the department heads concerned.

To do this means more than appears on the surface. It means that every assembly of figures, either of costs of production in all its ramifications, of country wide sales, of branch selling costs, of engineering, general, and all other such must *signify* something. Every group of figures must represent some activity for which someone is responsible. And no two responsibilities should be mixed up in one exhibit of figures. Two or more exhibits of figures, however, may be made for any one responsibility.

The main point is that no comptroller's department onto its job can afford these days to be "figure butchers," meaning the chopping up together of a lot of figures which lead nowhere and mean nothing. The comptroller himself should know enough about the jobs of every other department head to be able to talk to each in his own language. And the staff of the comptroller should likewise know enough about the ramifications of the business to recognize good from bad figures as they are assembled.

Do not mistake the object of this specification of knowledge necessary on the part of the comptroller and his staff as meaning anything beyond the permitting of intelligent compilation and interpretation of figures. Under no circumstances whatever should the comptroller or any of his staff presume to tell other department heads what they should do, as this would be fatal. Not only would it irritate the department heads, but it would also usurp the prerogatives of the chief executive. In fact, *interpretation is even a long way from advice.*

Use of Statements. What is to be gained by compiling really good figures if no one uses them? Therefore, after preparing perfectly fine and prompt records of results, the next great duty of the comptroller is to get them used. In most cases this is a real job.

Every comptroller must sell his wares. It is not enough to prepare fine statements and think the job is done. It has only started. It is up to the comptroller to interpret the results in clean-cut résumés and then follow through with enough contact to see that action is taken—not from a forcing standpoint, but from a standpoint of the great value lost to the company if the points brought out by the figures are not acted upon. This takes tact, salesmanship and a real human spirit of cooperation.

Personal Characteristics of Comptroller. At this point, let us think of the characteristics of the comptroller as an individual. Here is a man who has under his control the assembling of figures which present the results accomplished by everyone. Much good or much damage can be done by the comptroller as a result of the way he handles these figures, the way he presents them, and the way he talks about them.

It is obvious that the personality of the comptroller must be human in every respect. He must be sympathetic and still firm. He must be one who will study and present his points from the standpoint of absolute cooperation. He must guard against sharp words and any derogatory remarks.

In other words, he must be an honest, straightforward, cooperative and constructive type of individual, always ready to assist and always thinking of ways and scheming to help all of his associates to produce better results.

Exercise of Responsibility. The comptroller may exercise his responsibility in two ways as specified in the manual: first, by direct jurisdiction, and second, by functional jurisdiction. In this connection there have been many *impasses* avoided by this second method of jurisdiction—functional. It may pay us, therefore, to discuss this in greater detail.

Granting for the time being that the comptroller should have control over all office procedures, it is quite out of the question for the comptroller to have any direct jurisdiction in offices other than his own; as, for instance, the selling department offices. No man can serve two masters, neither can two masters direct one man. Therefore, the actual physical jurisdiction of office work must quite necessarily belong to the head of whatever office is in question.

But, if any degree of standardization is to be maintained, a complete avoidance of duplication of work accomplished, and the greatest efficiency of office operation reached, the matter of what records are to be kept, the equipment to be used, and all such features in every office must come under the indirect or functional jurisdiction of some central head, preferably the comptroller.

It is not unusual, when no central control has before existed, to find perhaps scores of reports and records which may finally be dropped on account of similarity or because their usefulness has passed. A central control exists to guard against such a condition, and still to give everyone everything they need in the shape of reports and records.

It is to be conceived, therefore, that the comptroller, an individual trained and specializing in accounting methods, in report compilation and presentation, in office procedures and all such mechanisms, is the logical person to be the central clearing house for all office procedures, either by virtue of direct jurisdiction as in his immediate department, or by functional jurisdiction throughout all departments where the physical or direct supervision is centered in those departments.

Executive Relations of Comptroller. The comptroller must be an individual in whom great confidence may be reposed in respect to secrecy as to projected plans affecting any phase of the business. An executive often wishes to consider certain changes in terms of dollars. The comptroller is consulted, asked to transpose such thoughts into dollar terms. In all such cases he must be secretive without affecting his relations with others. And also, may I add, without becoming subject to any enlargement of his cranium because of the feeling that he is a confidant or special adviser to the chief, when as a matter of fact he is simply the only one who has the figures to give. If he can develop into a real advisor, more power to him. But such a development will come only through his becoming a tower of strength for his chief because of a well-balanced business head, rather than through the route of happening to be the only one who has the figures desired by the chief. If, however, the comptroller *does* perfect himself in his knowledge of the business, and develops a clear-headed, clean-cut business mind, no individual has a

more wonderful opportunity to develop into really valuable executive timber.

Duties of Comptroller. Let us pass now to the specific duties of the comptroller as shown in the manual presented above:

Duty 1, to supervise all subsidiary divisions of his department, is obvious. Later on, a definite discussion of these divisions will bring out more clearly the organization of the comptroller's own department and his relation to other departments.

Duty 2, to keep down the costs of record and office work, is liable to hit many comptrollers rather hard. It is so easy to check up other departments but forget *our own costs*.

Duty 3 means that the comptroller must be fully informed as to all kinds of labor-saving devices for office work. This requires not only constant contact with manufacturers of devices but also attendance at business shows, and all such means of keeping up-to-date.

Duty 4, standardization of methods of record procedure, is of utmost importance, as it includes also the problem of man power, the training of clerks whereby they may interchange at any time, and all such. Also, consolidation of accounts for statement purposes requires a high degree of standardization.

Duty 5, to standardize office procedure, is a natural result of keeping up-to-date on office devices, and of studying the standardization of all kinds of clerical methods.

Duty 6 is very important. This calls for approval of all forms before adoption by any department. The performance of this duty saves thousands of dollars for any company, as it provides a definite safeguard against the use of forms which entirely or nearly duplicate others, against the setting up of forms when something better may be substituted, against forms which may report items which, with slight alteration, may be included with some other information, and so on.

Duty 7, to approve all requisitions for printed matter, is for two main purposes:

a. To stop or limit orders for printing of forms which are about to be changed.

b. To assure the carrying out of Duty 6 in cases where certain other department heads may attempt to "railroad" a form which has not been approved by the comptroller.

Duty 8 is that of supervising inventories. This duty is, or should be, indisputable. Actually, an inventory is a form of audit. Actually also, the methods of taking an inventory are largely clerical in nature, both as to the forms to be used and as to the pricing thereof.

Duty 9, that of the preparation of all tax reports, is a natural function of the comptroller. True enough the legal fraternity has to a considerable extent become involved; but this would probably never have happened, to the extent that it has, were it not for war-time experiences.

But, even though there probably might be more or less necessity for contact with the legal side of the business, the great preponderance of work in respect to taxes must always be done by the comptroller's department.

If so, this department should perfect itself in its knowledge of tax requirements and consult the legal departments only for advice on certain points.

Duty 10 is that of the preparation of all forecasts and budgets. In the carrying out of this duty there occurs the natural function of preparing a picture of the future in such manner that the actual accomplishments may be chalked up against the forecasts, and real value be obtained from the comparison.

In carrying out this duty the comptroller's department works closely of course with all other departments. All quotas, sales, manufacturing and other items must come from other departments; therefore, all forecasts and budgets become a real matter of cooperation with the comptroller's department the central point.

Duty 11 is that of keeping in constant touch with everyone from whom it may be determined in what manner the comptroller's department may be of the greatest assistance to the line departments.

Duty 12 is that of the interpretation of all reports and statements. This has been previously discussed.

Duty 13 covers the statistical function of the business other than the regular reports. It includes the many products of a tabulating department, covering all sorts of sales and manufacturing statistics and their presentation in either report or graphic form or both. The one great factor in the carrying out of this duty is the real working knowledge of the necessary information required by every department in order to better its results. Graphs, statements, reports and analyses which merely gratify curiosity or whim have no place in this category.

Duty 14 implies that all auditing is strictly a function of the comptroller's department, and such a fact should be specifically mentioned. It is taken for granted that the comptroller's department is responsible for audits of all kinds which safeguard the integrity of all disbursements by definitely approved vouchers, which vouchers pass to the treasury department for payment. This duty is specifically set forth under responsibilities of the Comptroller.

Duty 15 covers the performance of any special investigation required by the directors or officers of the company.

Duties 16 and 17 are very important. No department is possessed of so much information as to the probable results to be obtained from capital outlay as is the comptroller's, provided it has maintained the full knowledge of operations that has been described in the foregoing.

It is perfectly reasonable to expect the comptroller's department to audit a projected move as it audits moves which have already been made. Further, it is well known that capital expenditures made without a continual check always run over estimates more or less; many times through lack of knowledge of how the cost is mounting. At other times an excess cost is incurred deliberately. In all cases, a close check-up should be a continuous duty of the comptroller's department.

The comptroller does not approve or disapprove projected capital expenditures. He simply endorses an idea as to their earning value to the company. After this, when all the facts are known, it is up to the general management to make its decision.

Organization of Comptroller's Department. To carry out all the foregoing responsibilities, there is need that the comptroller's department itself be well organized. As has been stated, the comptroller discussed in this paper is in a large company. Basic characteristics, however, apply equally to large and small companies. It would be very easy to condense all that is described in this paper into a set-up for a small company, simply by combining operations.

The carrying out of all the preceding would indicate subdivisions of the comptroller's department along the following lines:

1. *General Accounting.* General ledgers, journals, etc.
2. *Accounts Payable.* Certification of all vouchers for disbursements.
3. *Accounts Receivable.* All customer accounts.
4. *Invoices.* Invoicing of all sales.
5. *Claims.* Custody and disposition of all claims of any nature.
6. *Sales Records.* Accounting for all sales.
7. *Cost Accounting.* Responsibility for cost accounting through either direct or functional jurisdiction, but always responsibility for the methods of same.
8. *Timekeeping.*
9. *Pay Rolls.* Direct or functional control of all timekeeping and pay rolls to fulfill integrity of pay rolls and of accounting procedures.
10. *Inventories.* Functional control to assure accuracy of physical count, pricing and grouping. This includes perpetual and physical inventories.
11. *Coding and Tabulating.* Where electrical accounting is used and where details are tabulated at central or decentralized points.
12. *Methods of Office Procedure and Forms.* Responsibility for all office methods and preparation or approval of all forms, etc.
13. *Forecasts and Budgets.* Assembly and presentation of all forecasts and budgets.
14. *Auditing (Including Traveling Auditors).* All auditing not otherwise automatically provided for, such as in accounts payable division.
15. *District Accounting.* Responsibility of a functional nature for all accounting outside of home office.
16. *Statistics.* All regular and special statistics in statement or graph form.
17. *Office Operation.* Responsibility for all office services which come under jurisdiction of comptroller's department, including: janitors, phone service, files, stenographers, messengers, etc.
18. *Cost Methods.* Study and installation of cost methods in all departments of the business.
19. *Tax Reports.* Preparation of all tax reports.
20. *Miscellaneous.* Royalties, dividend and capital stock records, group insurance and other employee records, contract files and records, appropriation records, special assignments.

General Comments. The comptroller is a staff officer. He can have authority only over his own organization and through a functional channel over methods of doing record and office work. His contact with all other department heads is for the purpose of providing knowledge, without opinions of the actual operation of the departments.

The records which are the responsibility of and under control of the comptroller are those of a financial and statistical nature. Corporate records, other than possibly those of capital stock, will fall outside his domain.

While the comptroller must be very deeply concerned with all investments of the company, of a plant or capital nature, he may or may not be concerned with other investments, unless such investments are in the nature of broadening the facilities of his company, such as in other manufacturing corporations. And, he may also be vitally interested in investing in other companies for the purpose of increasing the hold of his own company on prospective business.

The comptroller, being of an analytical nature, is logically the one to examine and report on all projects where an investment in the same depends on operating results to produce a return on the money invested. Other investments, however, such as bonds, etc., require no attention from the comptroller, being entirely of a financial nature.

The comptroller may well have the responsibility for use and occupancy insurance and for compensation and liability insurance, since these depend on inventory and payroll records. This does not necessarily cover contracting for the same, as such function may better be included with the handling of all other insurance by some other officer.

The Ideal Comptroller. If we may picture the comptroller and his department as fulfilling a staff function, controlling directly or indirectly all methods and operations of records and office procedure which is so intimately tied up with records, giving facts intelligently as to current results with forecasts of the future, helping every line officer in every possible manner to better results through the interpretation of what is actually taking place, we can picture an officer who can, if he will, make himself a tower of strength second to none in the management of a business.

THE FUNCTIONS OF THE AUDITOR

BY C. E. JARCHOW, *Assistant Comptroller, International Harvester Company*

The term "auditor" is frequently used as a designation of the accounting officer in complete charge of all accounting activities. This is particularly true in small companies. However, we refer here to the accounting officer in charge of that special branch of accounting work which generally comes under the heading of "audits and investigations."

It goes without saying that audits and investigations are an important accounting activity in all businesses. In a small business the work is frequently done by the same individual who is responsible for other accounting work. In a large business it is of sufficient importance to warrant the creation of a special department looking after that branch of the work.

Generally speaking, the auditor, as used in this sense, should report to the comptroller or possibly to the chief accountant or general auditor, depending upon the form of organization. In some cases the auditor or chief of internal audits, as he might be called, reports to the treasurer, but this form of organization does not insure the same degree of financial control.

Responsibilities of the Auditor. The responsibilities of the auditor will naturally overlap somewhat those of other accounting executives. They

include the verification of all records and a more or less constant review of various departmental activities, particularly in their ultimate effect upon company finances. The work of the auditor should not be confined to the mere checking of the figures, but should go beyond this and include the study and interpretation of the results of operations.

In considering some of the specific responsibilities of the auditor, let us assume a typical business, manufacturing and selling a certain article, in which his duties might be divided into three principal classifications:

1. Sales and distribution.
2. Manufacturing.
3. Head office.

In the sales and distribution division let us further assume that the business is conducted through *branch houses*, located in different parts of the country, selling goods, making collections, keeping records of account, etc. The branch organization consists of a branch manager, in charge of sales and collection activities, and an office manager in charge of accounting and financial work reporting to the comptroller or general auditor. The work of the auditor with respect to branch houses will include the verification of cash receipts and disbursements, occasional verification of inventories, accounts and bills receivable, and other assets and liabilities. In addition to this, he will ascertain whether or not branch managers are departing from sales policies laid down by the home office. It is entirely possible that a branch may be obtaining a large volume of business by undue extension of credit, or by making promises or guarantees contrary to these policies. This should be set out in the report of the traveling auditor and brought to the attention of the officer in charge of the sales division.

The auditor will assume supervision over the office personnel. He will ascertain whether or not the accounting system and the methods of internal check are as good as they might be; whether or not full advantage has been taken of modern office appliances, etc.

In the *manufacturing end* of the business, some of the functions I am going to mention might possibly come under the cost accountant, if there happens to be one.

The function of the auditor with regard to the manufacturing division will include the verification of factory records, occasional verification of inventories and basis of valuation. The method of accounting for the receipt and storage of materials, and for the issuance of materials to factory departments should be reviewed. The system employed for releasing materials from the factory should be investigated to guard against materials being taken from the plant without proper authorization.

The safeguarding of payrolls should be carefully reviewed. The auditor should look into capital additions, see that they are properly authorized, that amounts spent are within the appropriation and charged to the proper account.

As for the operating methods at the factory, the auditor should from time to time make studies of the relative efficiency of one plant with another and of the various departments within the same factory. Naturally, he is not

expected to make recommendations which would ordinarily come within the scope of the engineering department; but as there are many matters which will come to his attention he should be in a position to suggest improvements in factory methods, possible reductions in cost, etc.

The auditor's function at the *head office* of the business will include the periodical verification of cash and securities, inventories, receivables and other assets and liabilities not included in the audits at branch houses and plants. In addition to this he will make special investigations of any phase of the company's business that might demand attention.

Other special matters which should come within the scope of the auditor are:

1. Following up long-term contracts to see that no feature of the contract is overlooked.
2. Reviewing, periodically, special agreements such as royalty agreements, etc.
3. Inquiring into the sufficiency of the amount of insurance carried, into bonding of employees, etc.
4. Reviewing work done in other departments of the business to ascertain whether or not a duplication of effort exists, or whether some part of the work in one department cannot be done to better advantage in another.
5. Looking into methods of office routine and modern appliances to see that full advantage is being taken of them.

The natural line of promotion for the auditor will be to the position of chief accountant, general auditor or comptroller. The opportunities which the auditor has for reviewing many phases of the business should fit him for these positions.

The relationship of the auditor to the public auditor depends largely upon the thoroughness of internal audits. If a strong audit division is maintained within the company, it goes without saying that the public accountant need not make the same detailed verifications, that would otherwise be necessary.

FUNCTIONS OF THE CHIEF ACCOUNTANT

By ARTHUR PERROW, *General Auditor, Illinois Bell Telephone Company*

One of the outstanding functions of the chief accountant, that is, the chief accounting officer, regardless of whether he be called general auditor, chief accountant or some other title, is, with the cooperation of his superiors and subordinates, *to have departments know the services* which the accounting department stands ready to render to the production, sales, and other operating units. In other words, the accounting department must sell its important but sometimes more obscure services of historical analyses, comparative data of sales and costs, economic forecasts of future trends of the particular business, as well as business generally, etc., statistical compasses without which true success in any enterprise is difficult, if not impossible, to achieve and maintain.

It should be borne in mind that a *real distinction exists between accounting and auditing*. It might be said that accounting is the basis of principles and procedure, combining factors of efficiency and economy and having in view the ultimate effect of any proposal on the income statement or balance sheet. Auditing work, on the other hand, is intended to verify the processes set in motion by the accountant and insure that every approved method and procedure is actually being carried out, that every loop hole is protected against dishonesty or falsification of data. The chief accountant, therefore, should have active supervision of the accounting department including charge of the general books and other records. He should be responsible for the application of accounting principles or methods of procedure including cost accounting both as applicable to (a) manufacturing or production, and (b) selling or administration. He should be responsible for such a classification of accounts (approved by the comptroller) as will prove a proper framework for securing the information to be presented to the executives with a minimum of delay, in the form of suitable periodic reports.

Centralization of Accounting. In addition to his supervision of the accounting department, the chief accountant, acting through the comptroller, has functional control of the accounting records in all units of the business. The functions of the chief accountant depend largely upon whether accounting control is centralized. The present tendency seems to be toward centralization of accounting control in the general offices of the company, because the records can be brought under the direct supervision of the chief accountant (and therefore under the indirect supervision of the comptroller), which tends to promote accuracy and efficiency. As the volume of work increases, higher grade supervisors can be employed with the resultant opportunities for greater initiative and the development of division heads and officers of the company. Finally a large volume of work thus concentrated permits the release of man power for better use by securing mechanical equipment and other time-saving devices.

Of course, centralization should not be carried out to the extent of removing all administrative data from the local forces. A proper system of reports for the guidance of the local people should be maintained in order to minimize this condition.

It has been said that "accounting serves to rationalize business administration." The chief accountant should see to it that the principles of accountancy have been extended to every department of the organization, that current records are made of purchasing and production methods and costs, marketing, personnel, investment, income, and other related matters. In this respect the chief accountant recognizes that the success of the enterprise is dependent upon the costs of production and marketing being reasonable, that the cost level of the business is in line with a figure which will permit of competition. These proper prices will be established by effecting economies in the way of increased efficiency and reduction of waste, which can be measured only through accounting data.

Relation to Office Manager. The head of the accounting department should not be limited in the organizing of his entire department and ordinarily should supervise, indirectly, all related activities. In order to relieve him of

many details common to several divisions, it might be more economical to have an office manager reporting directly to the comptroller.

It has proved satisfactory to have the office manager take charge of a central stenographic bureau, incoming and outgoing mail, the employment of office boys; to be custodian of office supplies; record absences, tardiness, etc., thereby insuring uniformity of policy throughout the department or the company. Therefore, the question as to whether or not he should report to the chief accountant or comptroller depends entirely upon the amount and kind of work which can be assigned the office manager and, also, upon the personality of such an individual.

Research Work. It would seem that, with the increasing accounting complications of business and the demand for ready and significant data for the guidance of executives, research work should be regarded as an indisputable activity of the chief accountant's staff. Of course, it would depend upon the size and nature of the business, the availability of analysts on the chief accountant's staff, the cost and use made of such research work, etc. Keeping in touch with what is going on in other industries will result in more and better cooperation between industrialists, thereby helping to lubricate this great business machine which is moving forward, gaining momentum and effectiveness day by day.

The accounting analysts can contribute much toward keeping executives in touch with the best current thought on the many "hows" of steering a successful business enterprise. Further, it should be generally agreed that methods, of say ten years ago, are more or less obsolete today. The increasing tendency to use statistical analyses makes it incumbent upon the accountant to introduce the most scientific methods of accounting procedure so that statistical deductions will be most significant.

Financial Statements. Proper financing depends entirely upon correct accounting which underlies the determination of company policy. Among items which relate to both accounting and finance are depreciation, treatment of reserves, good will, valuation, budgetary matters, stock and bond issues, handling of sinking funds, redemption of outstanding obligations, etc. Therefore, in case the accounting and financial organizations are under the direction of a comptroller, these data which combine accounting and financial facts might preferably be prepared by the chief accountant in collaboration with the treasurer, but approved by the comptroller before being distributed in report form.

Status of Chief Accountant. The chief accountant whom I have been endeavoring to portray is already well equipped to handle almost any kind of a job and should be particularly well qualified for promotion to the position of comptroller. His contacts with the heads of the various departments as well as his numerous other activities should have been more far-reaching than those of any other subordinate of the comptroller so that, logically, the chief accountant is the comptroller's "right-hand man," conversant with accounting, financial, auditing, and other related activities of the entire department.

Accountancy is a division of business which calls for men of initiative, who have a constructive turn of mind. If the accountant avails himself of his

opportunity, his progress should not be restricted. Here, however, we have a personnel problem. If the chief accountant is by education and experience the purely technical type of personality who does not invite contacts with other officials, then it might be better to choose for the comptroller the executive type who, although perhaps lacking accounting technique, possesses a personality and general business acumen more in line with the needs of that executive position. But it is assumed that such a situation would be obviated by the selection of the proper person for the position of chief accountant, where the desirable personality referred to is also requisite to best company results.

Relation to Statistics and Budgets. The chief accountant should so design the accounting structure as to permit the compilation of significant statistical data. Therefore, it follows that the chief accountant should consider whether any proposed accounting method lends itself to ready statistical analysis of units of quantities, costs, time and place. All business is affected, more or less, by internal and external factors, and statistics should disclose what is going on. The raw material of truth is facts and just those facts are the stepping stones to right decisions.

If the business is sufficiently complicated, a statistician should be on the chief accountant's staff, whose duties would include the scientific marshalling of important data for the ready guidance of executives. In large companies the statistician works in close cooperation with the chief accountant but may report directly to the comptroller. Graphic presentation is a comparatively new equipment in the ranks of industry and is becoming increasingly indispensable. The accountant plays no small part in the development and use of those accounting facts which should convincingly suggest to the heads of the respective departments the necessity for particular action. The chief accountant should keep in touch with the so-called forces of the business cycle; that is, just how the company's operations have been and will be affected by the liquidation, depression, revival and prosperity of general business. Without this information he cannot talk the present day language of the executives.

Upon the data being received by the comptroller for coordination of the departmental budgets, the chief accountant should completely analyze the proposed program in the light of available information and advise the comptroller of the result of his critical analysis. The accounting and statistical points raised by the chief accountant will probably be referred to the budget committee by the comptroller. After the budget is approved, it becomes the function of the chief accountant to supervise the periodic comparisons of estimates and actual results, advising the comptroller currently so that the latter will be acquainted with all departures from the approved program and either have such differences reconciled or take executive action in the matter—to the president or general manager.

CHAPTER V

CORPORATE FINANCING

BY A. C. HODGE, *A. G. Becker & Co.*

Introduction. The purpose of this chapter is to deal with some of the problems faced by the financial executive in connection with securing and conserving capital to be employed in carrying on corporate activities. Capital funds to be employed by a corporation must be obtained from savings, either of the corporation itself or of individuals. If obtained from outside, capital may be secured from the sale of securities (a) direct to the individual investor, as has been done in a few cases by utilities and by some new and small corporations; (b) to the individual investor through the medium of the investment banker; or (c) to institutional investors, either direct or, more usually, through the investment banker. Only in rare cases is it either possible or desirable to secure outside capital without employing the investment banker as a middleman.

The problem of securing capital for corporate use is continually changing in aspect, being affected by the business cycle, the purchasing power of the dollar, the rise of new underwriting and distributing agencies, the development of new institutional investors, and in fact, by any change in the industrial or financial structure or in the investment habits of individuals. For this reason, it seems desirable to preface our discussion of this problem with a brief resume of the trend of industrial financing during the past decade.

Recent History. The enormous demands on industry brought about by the war naturally resulted in a very great expansion of credit in the United States between 1915 and 1918. This took the form of long-time financing as well as of commercial credit, being greatly facilitated by the operation of the new Federal Reserve System. This period was followed by one of deflation and contraction of credit, a logical reaction and entirely to be expected. Many of the strongest concerns in the country, however, failed to adjust themselves to conditions quickly enough. This was a hectic period for the bankers, who found themselves extensively engaged in rescue parties. Credit resources of commercial banks were strained to the limit. Companies who had not been borrowers for many years had many millions outstanding in commercial paper at 8 per cent. Much temporary financing was done in the form of short-term notes at high rates of interest. Preferred stock bearing 8 per cent dividend requirements and callable at high figures was sold, often at a considerable discount, and long-time bonds bearing coupons at 7 per cent and higher were only too common.

All this, of course, was tremendously expensive, but a most salutary lesson. The year 1921 marked the beginning of a remarkable evolution in management, with respect to planning and control. In most of the large and progressive companies, definite organization plans, defining authority and responsibility of executives, were adopted. Careful studies of procedure were made, and written standards of procedure were used to facilitate and control routine jobs. Complete and efficient budget systems were installed, making possible the establishment of standards of performance and a check on their attainment, so that careful planning of sales, of production, of purchasing, of expenses, became common, and financial requirements could be predetermined with remarkable accuracy. Attention to personnel problems, stimulated by war-time activities, became general, with the result that men were more carefully selected, more adequately trained for managerial responsibility, and provided with more direct and effective incentives.

The resulting increase in efficient management soon made itself felt in many ways. It made possible considerably increased production at lowered cost. In connection with greatly improved transportation it made possible a much higher turnover of capital, especially working capital. Competition became more effective and consequently more severe, so that business entered into a period of "selective prosperity," in which the very strong and well-managed companies made large profits and the weaker ones found the going very hard. The low-cost manufacturer, or the one who possessed a specialty, and the retailer, who could buy at preferential prices or was in a position to render special services, enjoyed the lion's share of the profits.

The struggle which had been going on for years for control of the consumer market became much more intense, with the manufacturers, the large-scale retailers, and the wholesale-retail contingent each spending large sums in various forms of publicity to influence the consumer in their favor. With the new methods in management it was found that much larger business units could be managed with equal efficiency, and could afford a higher quality of managerial ability without a corresponding increase in expense. Also, increased size meant improved credit, greater possibilities in securing publicity, and in many cases improved purchasing power, in addition to other economies of large-scale operation. These facts led to a marked tendency toward an increase in the size of the business unit. Individual businesses made greater efforts to secure volume, and the movement toward consolidation took on a new impetus. This movement is too familiar a phenomenon to require comment. Chain stores expanded and took over other chains. Large groups of department stores were brought under common ownership. Every industry had its mergers, most of them involving new financing. The greatly increased size of business units and the large amount of capital involved tended to bring about a greater degree of separation between management and ownership.

All of these developments have had their effects, either directly or indirectly, on the financial history of the country since 1921. It is difficult to discuss these effects in any definite order, but one which seems to suggest itself first is the change which took place in the source of funds employed by

companies in their current operations. We have noted that during the period of adjustment many companies borrowed very heavily from commercial banks and through the sale of their paper on the open market. After taking inventory losses incident to deflation many of these companies found themselves in an unfavorable position with respect to working capital, and took the first opportunity to secure additional working capital through the sale of securities. These were sometimes short-time notes, usually from three to five years, sometimes bonds of longer maturity and sometimes preferred stock. As has been pointed out, all of these securities were at high rates of return, and were callable at a considerable premium, if at all. Having secured more or less adequate working capital through relatively long-term financing, these businesses set to work to avoid any repetition of their recent financial difficulties. Because of more scientific planning, and the great improvement which took place in the service rendered by the railroads, the average business was able to operate with inventories much smaller in proportion to its volume of business than formerly. Also, boards of directors had learned a lesson in conservatism, and were careful not to pay dividends in such amount as would threaten the working capital of the business. By 1925 a great many of the companies who had borrowed heavily from the banks or on the open market were in a position to be practically independent of such sources of credit. The resulting reduction in the amount of commercial loans set free large amounts of funds for the purchase of high-grade securities, for call loans to brokers, and for collateral loans to individual investors.

At the same time the new revolution in business had increased the productivity of the individual and had given him greater purchasing power, so that a large number of additional small investors had come into the market. The result of these factors was a market which would absorb a vast amount of securities at increasingly high prices. Many corporations which had not previously funded their current liabilities and provided themselves with ample working capital now proceeded to do so by means of long-time obligations or stock issues. A large number of companies took the opportunity to strengthen and solidify their financial position, and to improve their financial structure. The flotation of securities was dangerously easy, and it has since appeared that some of the issues did not represent sound investments. At any rate, with the downward turn of the business cycle and the accompanying debacle in the securities market, this phase passed into history. Like every other phase of history, it left certain legacies, and these condition the problems which face the financial executives of the present with regard to long-term financing. Some of the tendencies which appear are:

1. A greatly increased interest on the part of the investing public in common stocks as compared with securities with a fixed yield. This interest extends to any device which promises an opportunity to share in profits, such as convertibility and participating features, options, warrants, and the like, on senior securities.

2. A change in the methods of corporation financing. Many corporations have substituted common and preferred stocks for fixed obligations. This

has been done not only by means of public issues but also by retaining cash and declaring stock dividends, and by the issue of rights to stockholders. Such corporations have greatly strengthened their financial position and many of them have become large investors.

3. Greatly increased emphasis on distribution and marketability of securities. Both the investor and the issuing corporation have come to place more importance on a wide distribution, listing, and a ready market.

4. An increase in the number and importance of investing institutions and institutional investors.

5. The development of "department store" banking, especially the establishment of investment banking institutions in connection with large commercial banks.

Present Institutional Structure. The financial executive, when he has occasion to go to the market for capital, finds a number of different types of institutions performing their own special functions in the capital market. These institutions may be listed as follows:

1. The investment banker.
2. Brokers and stock exchanges.
3. Investing institutions.
 - a. Savings bank.
 - b. Investment trust.
 - c. Savings department in commercial bank.
 - d. Trust company.
 - e. Mortgage bank.
4. Institutional investors.
 - a. Life insurance company.
 - b. Corporation.
 - c. Commercial bank.
 - d. Eleemosynary institution.

Naturally, the corporation's only direct contact with the capital market is made through the investment banker who underwrites its security offering. This investment banker and his associates make it their business to pass on the securities to the investors, institutional as well as individual. Once the securities have been issued, the broker and the stock exchanges furnish a market, thus making them marketable from the viewpoint of the investor.

Functions of the Investment Banker. Investment bankers are security middlemen. On the one hand, they gather the funds of the community either directly from investors or through intermediate institutions. On the other hand, they establish contact with those in need of such capital, and direct its flow into the most promising channels. It is through these middlemen that the bulk of the new capital raised in the American market is secured. Investment bankers may be classed as wholesalers, retailers, and dealers (small retailers). Most of the larger investment houses are at present a combination of wholesaler and retailer. They buy, alone or with associates, entire issues of securities and sell them both at wholesale (through other retailers and dealers) and at retail (direct to investors). The list of investment bankers has been swelled in the past few years through the formation of securities subsidiaries by practically all of the large city banks.

The investment banker has a responsibility on one hand to the issuing company to devise the soundest and safest way of securing the required capital. He has an equally strong responsibility on the other hand to his investing clientele to protect them against unsound investments. If the securities issued are not to be listed, the investment banker and his associates constitute the only market in which the investor can liquidate his holdings. And even if they are listed, it is his responsibility to maintain a market on the securities, until they have become somewhat seasoned, and to exercise a continual sponsorship as long as the securities are outstanding. To make such sponsorship effective, it is necessary for the banking house to maintain a close relationship with the issuing corporation. This usually takes the form of representation on the board of directors. Such representation is practically universal in case of stock issues, usual in connection with long-term bonds or debentures, and less frequent in case of short-term notes.

It is not to be understood by this that the investment banker considers it any part of his duty to dictate the policy of the company. His object is only to make sure that no action is taken by the company which will needlessly weaken the position of the security holders.

Unless the demand for a given security by investors is spontaneously strong and active, the investment banker will have occasion to do a great deal of selling in order to maintain a healthy market for it. For this reason it is wise for the issuing corporation to choose a banking house whose organization for distributing securities is thoroughly adequate. Some of the most powerful investment banking houses depend for the most part on their wholesale distribution, and this is quite adequate where the securities in question are of a very large and favorably known company. In marketing the securities of a less known company, however, where it is necessary to inform the investors concerning the soundness of the company and its securities, it is advantageous for the investment banking house to have a strong retailing organization of its own.

Corporate Capitalization. In the current chapter no attempt is made to include a discussion of the financing or capital structure of utilities. This is a highly specialized field, and certain special considerations prevail which do not apply with the same force to industrial corporations. For this reason, the discussion here is confined to industrials.

In the recent refinancing by such companies, as well as in new financing, and in the financial set-up of consolidations recently effected, there is apparent a strong tendency toward simplification of the capital structure and toward the elimination or avoidance of heavy interest charges and dividend requirements. This is in line with the policy of conserving surplus and building up the stockholders' equity. It is, of course, inevitable that in corporate financing at any given time the form of security issued will be conditioned by the form of security temporarily in demand. Thus in 1927 and early 1928, a tremendous volume of refinancing was done by means of low-rate bonds, debentures, and serial notes. At the same time, there was a continually increasing demand by investors for common stocks and for preferred with special features providing for a possible share in profits. In the typical merger effected during this period and up to the time of the break in the

securities market, preferred stock was issued in part payment of the assets taken over, where in previous years bonds would have been used, and the greater part of such payments were made in common stock. Several such mergers were effected by the use of common stock alone. Common stock issued during the post-war period has been almost entirely of no par value. A "stated" value is ordinarily assigned to this common stock, and whatever asset value is received in excess of the stated value is shown in a capital surplus account. A number of large corporations also took advantage of the demand for stocks to substitute junior securities for funded debt and in many cases to retire preferred stock in favor of common with the result that, in the ensuing period of reduced profits, they found themselves in a very comfortable position financially, not being embarrassed by heavy fixed charges.

The tendency to make use of no-par stock and thereby add flexibility to the capital structure has also led to the use of "A" common stock of no par value to fill the place formerly occupied by par value preferred stock. This is discussed in a later paragraph.

Treatment of Intangibles Purchased. It has come to be quite generally recognized that there is no particular point to be gained by carrying more than a nominal valuation in the balance sheet for intangible assets, such as goodwill, trade-marks, water power rights, patents, and the like. Ratios computed by either commercial or investment bankers, for the purpose of rating the soundness of a company's position or for estimating what securities can conservatively be issued, invariably consider only the company's tangible assets. The psychological effect of a published statement is generally conceded to be better if intangibles are given only a nominal value. In recent mergers where companies taken over have received payment in cash and/or securities exceeding in value the value of their net tangible assets, the resulting valuation placed on the intangibles has usually been written off against capital surplus account, also known as contributed surplus. This account is created originally by placing a stated value on the no-par common stock and crediting capital surplus with the amount by which the total value of assets received for such stock exceeds the stated value. This practice with respect to intangibles results in a net worth figure on the balance sheet reflecting only the net tangible assets.

Securing Capital from Earnings. During the past five years or so, and up to the slump of 1929-1930, most of our large corporations showed excellent earnings. Many of them increased their cash dividends, but an examination of the balance sheets of such companies at the present time shows that for the most part a very conservative policy has been followed in the distribution of profits. Large reserves for contingencies have been built up, and earned surpluses have been accumulated to large amounts. One device that has been extensively employed by corporations with large surpluses and good earnings is that of supplementing the regular cash dividend on common stock with special stock dividends from time to time. This has the effect of ploughing earnings back into the business by reducing the surplus account and increasing the number of shares of common stock outstanding. It enables stockholders to turn a portion of their equity into cash through the

sale of the stock if they so desire. It does, of course, increase the number of shares upon which the regular cash dividend is to be paid, but there is always the possibility of cutting the regular dividend whenever any special need for conservation is apparent.

Financing from earnings has always been one of the recognized methods of securing capital, and the accumulation of capital through corporate saving has assumed considerable importance recently. The effects of this policy are evident in the strong financial position shown by the balance sheets of most of our large corporations after a year of reduced earnings.

Purposes of Long-term Financing. The purposes for which long-time financing is undertaken fall for the most part into six groups. They are:

1. To secure needed working capital.
2. To refund long-term obligations at maturity.
3. To refinance high-rate issues with low-rate financing.
4. To secure additional capital for permanent improvements and internal expansion.
5. To secure funds for the purchase of competing or complementary business establishments—consolidation.
6. To withdraw capital from the business, in order to diversify investment or to create a wider market for the company's stock.

Long-time Financing for Working Capital. Long-time financing to secure working capital might normally be expected to be undertaken only in exceptional cases, but it was common enough in 1921 and for a year or two afterward. A shortage of working capital, cramping the operations of a business and injuring its credit, may result from any of three causes: (1) losses incurred by the business; (2) conversion of working into fixed capital; (3) a too liberal payment of cash dividends on the company's stock. The period of deflation and readjustment forced most companies to take heavy inventory losses, thereby impairing their working capital. This condition made it very difficult for such companies to secure funds through commercial bankers or commercial paper houses, on account of their unfavorable current ratios. The needed working capital was secured, therefore, by issues of bonds, notes, or preferred stock, and those companies which did such financing as an emergency measure were forced to do it on a very costly basis. Later, after the most severe phase of the adjustment period had passed, other companies who had been able to secure needed funds through banks and commercial paper houses took the opportunity to sell securities to retire such loans and provide themselves with a safe amount of working capital. By 1924 or 1925 the greater part of such financing had been completed.

It sometimes occurs that a well-managed business has occasion to increase its investment in plant, and pays for such increase out of its current funds, thereby depleting working capital to a point lower than is desirable, so that long-time financing is necessary. In the last analysis, of course, such financing is really for the purchase of long-time assets, although directly it is to replenish working capital.

Refinancing. The refunding of high-rate issues with long-time low-rate financing was a very common practice from 1925 to 1929. It resulted very naturally from the very strong market for corporate securities which devel-

oped during that period, and such issues included rails, utilities, and municipals, as well as the general run of industrials. Securities were marketed at prices which not only reduced the interest rates of the post-war emergency financing but also enabled corporations to retire many of their securities issued prior to that time, even at fairly high call rates, with a distinct saving. 7 and 8 per cent preferreds were called at 110 and 115 and replaced by 5 per cent debentures. Three- and five-year notes were refunded with twenty- to fifty-year bonds, by ten- to twenty-year serial notes, and by preferred stock issues. Thus one great industrial sold \$30,000,000 of First Mortgage 4½ per cent Bonds, with a fifty-year maturity, priced at 95 to yield 4.76. Part of the proceeds of this issue was used to retire \$12,000,000 of 5½ per cent debentures issued in 1925 at 98½, and callable at 103½, as well as \$10,000,000 of cumulative preferred stock, sold in 1923 at 104½, and callable at 115. It was stated in the circular that the annual interest charges on the entire issue of bonds would be less than the interest and dividend requirements on the securities retired. Another big industrial refinanced \$64,500,000 of outstanding securities, including four different issues, through an issue of \$75,000,000 First Mortgage Sinking Fund 5 per cent bonds, sold at 101 to yield 4.95. Three of the issues retired bore 6 per cent coupons, and the other 5½ per cent. Here also the total interest requirements on the new issue of \$75,000,000 were less than the interest requirements on the \$64,500,000 retired.

As the demand for common stocks increased, in 1928 and 1929, a number of companies sold additional common stock, and employed the proceeds to retire bonds, debentures, notes, and preferred stocks. A considerable part of the aggregate of such stock issues was absorbed by the stockholders in the exercise of the rights which they received to purchase the new stock at a price below the offering.

Financing for Improvements and Expansion. It is obvious that any one piece of financing may have more than one purpose and usually does. Also, in attempting to trace trends in financing, it is often difficult to classify issues according to their purpose. When refinancing is contemplated, it is usually so stated in the circular. The same is true of the acquisition of one or more additional companies, or of a stock interest. But the phrase "and for other corporate purposes" may mean an addition to working capital, an investment in additional fixed assets, or some less usual purpose.

It is hard to form any estimate of the relative importance which addition to permanent capital assumed in industrial financing from 1922 to 1929. There is no question that it assumed an important place in the financing of railroads and of public utilities, though it is very doubtful if even here it ranks with refinancing. There are certain factors, however, which have tended to keep down the amount of financing for this purpose by industrials. For one thing, it is to be remembered that during the war and immediately following there was a great increase in plant facilities, so that after the period of readjustment a number of industries were suffering from overcapacity. Most of them still are. Another point to be noted is that companies which have had good earnings in the past few years have been keeping a large proportion of such earnings in the business, and have financed additions to capital

assets in this way. There have been a number of issue which assigned the erection of new plants as their primary purpose, but they have not been important in number or amount when considered as a part of the whole.

In connection with the matter of financing for internal expansion, it is interesting to note that there have been a few cases in which companies have done long-time financing for the purpose of building up and extending their systems of distribution. In one notable case this took the form of a gigantic advertising campaign. Such financing could not very well be done by means of bonds, since the asset acquired, if it can legitimately be capitalized, is certainly not a tangible one. It would be a natural reaction to expect a stock issue for this purpose, so that there might be no definite charge against earnings. In this case, however, the company's credit was so good and the market so strong that the financing was done by means of debentures with a $5\frac{1}{2}$ per cent coupon. As the bitter struggle for control of the consumer market continues, and as advertising media continue to multiply, it will not be surprising if we see further financing for this purpose. In fact, there is little doubt that this has been covered by the phrase other corporate purposes in more than one instance.

With regard to the class of securities desirable for the purpose of financing additions to long-time assets, this is conditioned to some extent by the nature of the demand for securities at the time the capital is required. It also depends on the existing capital structure and funded debt of the issuing company, and the amount and dependability of the company's net income. In some cases where the amount required is such that it can be obtained in a local market, the state laws with respect to personal property or other taxes may influence the form of the issue. As a matter of practice, the form of securities to be issued is something that can best be decided in consultation with the investment banker at the time it is desired to secure the capital.

Consolidations and Mergers. Financing for the purpose of effecting consolidations usually involves also the withdrawal of investment by some of the former owners, since family-owned businesses are sold to consolidations quite as often as to the investing public. In any given case, however, the primary purpose is easily determinable, and the two may well be discussed separately.

Disregarding the underlying economic causes for consolidations and mergers, it is sufficient for the present discussion to note that they have been very numerous in recent years, and that interest in such combinations was not ended by the collapse of the securities market. Several important mergers have been effected during 1930 through the exchange of stock for the assets of the company taken over. A revival in business and in the securities market will very probably lead to other large consolidations. Even in times of depression, the investment banker is offered opportunities to play his part in such combinations, regardless of whether the market permits any public offering of securities, and it is his task to weigh the merits and demerits of such plans. He must, therefore, be cognizant of conditions in a variety of industries, and of the changing factors which influence these conditions. He must know who are really able and farsighted men in an industry, and be ready to cooperate with them in any practicable fashion.

Mergers are sometimes brought about entirely or in the main through the exchange of securities among the stockholders of the business units involved, in which case there is little or no financing involved. More frequently, however, they involve the purchase, either outright or stock control, of certain companies by others. The company acquiring the other sometimes has sufficient available funds without additional financing. Where this is not the case, it may be possible and desirable for this company to secure all the funds required through an issue of bonds or debentures. In a large number of cases, however, financing for this purpose is accomplished at least in part through the use of stock. This may be preferred stock, par or no par, made attractive by a bonus of common, a warrant for the purchase of common, or by a convertible feature; or the financing may be done by a sale of *A* and *B* stock, usually of no-par, and sold separately or in combined units. In this case the *A* is usually preferred as to dividends, and may also be convertible into *B*, or even participating. Or in rare cases, the financing may be accomplished through the sale of common stock only. Thus there are a number of variations possible on the extent to which the public is invited to share in the risks of the new undertaking, as well as on the extent to which they may share in the potential profits.

When the securities market of 1928 to 1929 was at its height there were certain industries especially, in which profits had been large, and in which most of the earlier combinations had proved successful. The public was so eager to purchase the common stock or other securities bearing bonuses, warrants or rights to buy common, or convertible into common, in connection with new combinations in such industries, that there was occasion for the investment banker to be continually on guard against their over-optimism, as well as his own. That he was not always successful in this became only too evident later. Naturally, the depressed prices of such securities in 1930 is not a fair criterion of the soundness with which issues were priced, and some time must still elapse before this can be finally judged. It is clear enough, however, that competitive bidding for many such deals by investment banking houses resulted in the issue of securities at prices which were even then very hard to justify on any economic basis.

It is desirable for the business executive to remember, in negotiating for public financing, and in determining the price at which the company's stock is to be offered, that if it later becomes evident that the price at which the securities were sold to the public was unjustifiably high, it means not only a loss to the investors and a severe blow to their confidence in the underwriting house, but also a loss in prestige and goodwill on the part of the issuing company.

Financing to Diversify the Owner's Investment. The sixth purpose mentioned for which financing may be done is that of withdrawing funds from the business. Financing of this type constitutes one of the most important and interesting classes, both to the investment banker and to the investing public, and has assumed so much greater importance in the past few years that it deserves a very prominent place in any discussion of recent trends in financing. This is in general the process by which the public is today becoming a partner in a number of businesses which were formerly

closely held, and whose financial affairs were in most cases a complete secret to the public.

The typical situation which gives rise to this type of financing is one in which one man or a comparatively small group have built up a business without taking in any partnership capital outside of the limited group, until the business has come to have a high potential market value, either through continual reinvestment of earnings in the business, through an excellent earning record, or for both these reasons. In many such cases the business has a value, as reflected in its earning record, considerably greater than that reflected in the book value of its stock. Where such a situation exists, certain contingencies may arise which make it desirable for the members of the owning group to withdraw part of their capital, substituting for it funds furnished by the investing public.

One consideration which may influence the owners to this end is that the company has grown to such a size and the fortune which each of them has tied up in it has become so large that the stockholders feel it desirable to be able to diversify their investments to a greater extent than they have been able to do through the investment of their dividends. In fact, it is sometimes true that the expansion of the business has been so rapid that the cash dividends paid have been little in excess of the current requirements of the stockholders. If they can withdraw a part of their capital and at the same time create a market for the company's stock, they are not only in a position to diversify their investments by the reinvestment of the funds which they withdraw, but their remaining holdings in the company have gained appreciably in market value.

Importance of Marketability. This single point of marketability may very easily be the determining consideration in deciding to offer a portion of the company's stock to the public through an investment banker, as it is practically always one of considerable importance, even when incidental to the primary object of the financing. Thus the single owner or small group may have plenty of investments outside their own business but may at the same time feel that it would be desirable to market a small part of their stock holdings in order to establish for the remaining stock a market value commensurate with its earning power. Many companies have adopted the policy of encouraging their more responsible employees to purchase stock of the company, and in many cases this encouragement amounts to compulsion. This practice is very likely to help the morale of the employee, by making his interest to that extent identical with that of the company. It is, however, distinctly unfair if the only market for such stock is to be found among the present group of stockholders. The practice which prevails in most such cases, of paying a stockholding employee who is leaving the company the book value of his stock, usually deprives him of a considerable portion of the value of the stock, which value he has presumably helped to create. While we are considering the subject of marketability, it should be remembered that many closely owned corporations are so capitalized that each share of their common stock has a very high book value, and assuming the business to be successful, an even higher potential market value. Retiring this old stock, and issuing a much larger number of shares, which in most

cases would be without par value, takes the stock out of the class of "rich men's stocks" and makes it more available to the great body of investors.

Other Considerations Affecting Withdrawal of Owner's Investment. Sometimes, also, as one or more of the men who have built up the business and are its owners reach the age when they are thinking of retirement from active business and of putting their affairs in order against future contingencies, they are more easily led to realize that a public interest in the company, with a well-established market for its stock and with a strong investment banking house of national scope represented on its board of directors, will go a long way toward the continuity of the business and toward making its stock a desirable investment for their heirs.

It sometimes happens that a man has built up a business to the point where it represents a large estate, and wishes to retire from active participation, or even from taking any part in the management. Assuming that an entirely competent management has been developed, it is of course possible for him to do so. But men who have the ability to manage such a business successfully are also ambitious enough to be anxious for control. If the retiring owner or owners are willing to relinquish control in return for an amount of money representing the fair capitalized earning power of their holdings, the active management may call on the investment banker to work out a plan of financing which will secure the necessary funds from the public and still place the control in the hands of the managing group.

One contingency which often leads to the sale of an interest to the public is that of the death of the controlling stockholder in a closely held business. In such a case the active management remaining in the business will wish to secure control, for the reasons which have just been mentioned. There is also the additional reason that it is often embarrassing to the management to have control held by an estate. The writer recalls at least one case with which he was brought into close contact in which a highly able and successful management was so harassed by the combination of a credulous widow and an unscrupulous group of trustees that its members finally withdrew from the business. There is no intent to imply, of course, that such an extreme case is to be considered typical. It is fairly obvious, however, that it is more favorable to the management to have stock control either in its own group or divided between that group and a number of individual investors represented by a friendly banker.

Even though the deceased stockholder may not hold a controlling interest, there may still be considerations arising out of his death which will make some sort of public financing desirable. The estate may need to raise money to pay the inheritance tax. Also, the stock of the company may not be considered a suitable investment for the heirs, on account of its limited marketability, or because an inactive group of minority stockholders in a closely owned corporation cannot always be sure that the active majority is to be depended on to protect the interests of such minority.

Another consideration which may influence the owners of a closely held corporation in deciding to offer stock to the public is the trade advantages which may arise out of such an offering. Some of our great public utilities have long since realized the importance of attaching the goodwill of the public

and have carried on extensive campaigns for customer ownership. Manufacturing companies whose products are nationally distributed and nationally advertised may well find that to have their stock marketed nationally through a strong and favorably known investment banking house gives them added publicity of a favorable type. The same consideration applies to chain stores and mail order houses whose operations cover a wide territory. In these days when so much hinges on consumer goodwill, many business managers have come to attach considerable importance to favorable financial publicity, both through the distribution of the company's securities and of its commercial paper. A broadened interest in a company's securities is very likely to carry with it a broadened interest in its product, and such companies as are prepared to have the "searchlight of pitiless publicity" turned on them may well profit by the attention which they thus attract.

Methods Employed in Financing Withdrawals. Public financing for the purpose of withdrawing owner's investment may give rise to a variety of security issues. Where the withdrawal of funds is the primary object, and there is no desire to create a market for the company's stock, it may be accomplished through the use of bonds, debentures, or straight preferred stock, par or no par, provided the company's asset position and earnings record are such as to make the particular kind of issue in question a feasible one. Where the plan involves the creation and maintaining of a public market for the company's stock, however, its execution necessarily involves the issue of a sufficient amount of common stock to permit of public trading in it on one or more of the recognized exchanges. In any given situation this common stock will be placed on the market in whatever manner seems best adapted to the peculiar situation of the issuing company, and the trend of the current demand exercised by investors. In recent years such common stock is almost always of no par value, and the number of shares into which ownership is divided is such as to give each share a fairly low market value, on the theory that, other things being equal, there will be more general trading in a low-priced stock than in a high-priced one.

There is, of course, a variety of ways in which common stock may be issued, regardless of the purpose for which it is issued. It may be given as a bonus with bonds, notes, or preferred stock, thereby making such securities more attractive and improving the price at which they can be sold. Besides such a bonus, warrants entitling the holder to purchase a given number of shares of common at a certain price within a specified period may be given with the senior securities, or warrants may be attached and no bonus given. The issue of such stock warrants naturally requires holding in the treasury an amount of common sufficient to redeem them. A bonus of common may take the form of regular certificates issued along with the other securities involved, or it may take the form of a provision that so many shares of common will be issued whenever the first dividend on the common is declared. Another device employed to secure a greater price for the senior securities and to aid in getting common stock on the market is to make such securities convertible into common at a specified ratio, and within a time limit set. This again requires holding common stock in the treasury.

In case of stock warrants and convertibility features, it is quite usual to set the purchase price or the basis of convertibility at one figure up to a certain date, after which it changes to a basis more favorable to the common stock, to continue until another date set, and so on.

Another variation of the bonus plan is to sell units consisting of one unit of the senior security (bond, note, or share of preferred) and a certain number of shares of common, at a price which allots a certain value to the common. This has the merit of attributing somewhat more importance to the common stock than is the case where it is offered as a straight bonus.

A plan of financing which has come into quite general use in the past few years in cases where common stock is to be placed on the market is that of issuing two classes of stock, usually known as A and B stocks. Both these stocks are typically of no par value. The A stock will, as a rule, represent a fairly respectable equity in the tangible assets of the company, and will be preferred as to dividends for a certain amount per share per annum, these dividends being cumulative in most cases. Usually, also, it will be callable at a given amount per share, and preferred as to assets to a certain amount in case of liquidation. Such a stock may thus be in effect a no par preferred, although it will not in every case carry all the features mentioned. Usually the preferred dividend per share and the call price will give such stock a price per unit considerably less than \$100, the usual par of preferred stocks. The B stock does not as a rule have very much of an equity in the tangible assets of the company but is likely to approximate, at least roughly, the amount by which a valuation of the company based on its earning power exceeds the amount of its net tangible assets. It is, in other words, stock issued against the goodwill of the company. The value of such stock, at the time of its issue, is purely speculative, since it is not expected to pay dividends immediately, and its ultimate prospect of paying dividends depends on the future success of the business. It is fairly evident, however, that when the company has demonstrated its ability to earn a fair return on this B stock, and the stock itself has been on the market, sponsored by a strong investment banking house or syndicate, long enough to become "seasoned," the market value of the corporation's entire capital stock is likely to be considerably greater than it would have been with the same earning power while the stock remained closely held.

In the case of a corporation whose earning power has been well established it is of course possible to sell common stock alone, or if other securities are offered in the same piece of financing, to sell it independently of such other securities. So in the case of a B stock, such stock may be offered to the public quite independently of the A. More often, however, the offering is made in some sort of combination, such as those already mentioned. It may be given as a bonus on the A, with or without additional stock warrants, or it may be offered combined with the A stock into units, the B stock being detachable immediately, at a definite future date, or upon the occurrence of some stated contingency, such as the closing of the underwriting syndicate or the payment of the first dividend on the B stock. Also, when A and B stocks are issued, it is quite usual to enhance the attractiveness of the com-

bined offering by making the A stock convertible into the B, either share for share, or on some other logical basis.

Stock with No Par Value. In discussing the use of common stocks as employed in various types of financing we have assumed a general acceptance of no-par stock, and have not elected to treat it as a recent trend in financing. Its use is too well established and too familiar to all of us to require any particular discussion. It affords greater flexibility in effecting desirable readjustments in capital structures than did the old par-value stock, and obviates the necessity for the many elaborate fictions which appeared on the balance sheets and prospectuses in the good old days when the latter was in general use. It is true that one of our eminent economists recently attacked its use vigorously, making the assertion that it opened the way to many new iniquities in financing. But it is also true that in the very deals against which this gentleman fulminates, no attempt was made to conceal the facts, and he admits as much himself. Common stock, and for that matter other securities as well, depend for their value on a satisfactory trend of earnings, and this fact is clearly recognized by both bankers and investors. In cases where common stock financing works out to the disadvantage of the investors, it is simply because the bankers are honestly mistaken in their estimate of the future trend of earnings, and not because the use of no par value stock has enabled them to work any hocus-pocus on the investing public. The percentage of such cases is no higher today than it was before such stocks were employed, and the facts are set forth in much more frank and understandable fashion now than they formerly were.

Trends in Investor Demand. The foregoing discussion of methods by which common stocks may be placed in the hands of the public very readily suggests a definite trend in the market for investment securities. The trend in question has to do with the nature of the demand exercised by the investing public. The past few years have been years of real prosperity, in which nearly all of the strong and ably managed industries in this country have had good earning records. Individuals in general have had higher earnings purchasing power has increased and the standard of living has advanced. These factors have affected the attitude of investors in at least two respects. The first is that they have gained faith in the stability of management and of earning power in our large and well-known industries, and have come to feel that the preferred stock, or even the common stock of such an industry may be just as much an investment as a bond or debenture. Indeed, when a group of bankers can make a successful offering of a 6 per cent preferred stock to the public at 105, this being also the call figure of the stock, it would seem to indicate that some preferred stocks are considered better investments than some bonds.

The second respect in which the attitude of the investor has been modified is to be found in his demand for investments which carry with them the opportunity for speculative profits. The standard of living has risen to a point which constitutes a painful problem even for men whose earnings are comparatively high. The investor realizes that the strong market for securities has resulted in beating down the rate of return on high-grade securities to a very low point. At the same time, however, he wants the

chance of some action for his money. This accounts for the readiness with which the public has purchased securities which carry with them bonuses of common stock, warrants for the purchase of such stock, or the privilege of conversion into common stock. It also accounts for the fact that the investor will pay a better price for a bond bearing a low coupon rate and sold at a discount than he will for one bearing a higher rate and sold at par or at a premium. They have become so accustomed to seeing bond issues called long before maturity that the purchase of a bond at a discount appeals to them as an opportunity for a speculative profit, even though it is only a small one.

Responsibilities of the Investment Banker. This new attitude on the part of the investing public naturally received a severe setback from the very drastic deflation of values which has occurred in the past year (1929-1930). It was pointed out at an earlier point in this discussion that during the boom period investment bankers often purchased issues at what appeared to be unreasonably high prices, in accordance with the public demand which then existed for such securities. Naturally, investors who purchased such securities have in the majority of cases suffered a serious depreciation in the value of their holdings, provided they continued to hold them. Only future developments will make it possible to determine if the original offering prices were really unreasonably high. Whenever it eventually appears that such original offerings were overpriced, the result must inevitably be loss of goodwill to the corporation, and loss of prestige to the investment banker. This is true in spite of the fact that the securities were sold at a price in line with investor demand, and that the banker honestly considered them a sound investment.

The investment banker has a clearly defined and well-recognized function as a guiding factor in national and international industry. It is his task to guide the capital accumulated by potential investors into those channels in which it will prove most productive. It has already been pointed out that he has a double responsibility, on one hand to the issuing corporation and on the other to the investor, and that his survival and continued prosperity depend on discharging these responsibilities honestly and wisely. A temporary decline in the general price level of securities, due to a cyclical falling off in business activity and profits, does not prove him a false prophet. His real mistakes, however, do not remain hidden, and the character of his house must inevitably be judged in the long run by the record of the securities which it has offered. The other side of the picture is that the public, having at any time formed fairly definite ideas of the better-known investment banking houses, tends to have its opinion of the soundness of the issuing corporation colored somewhat by its opinion of the underwriting banker or banking group. The strength and reputation for conservatism of the investment banker should, therefore, be an important consideration in the mind of the executive who contemplates placing the securities of his company on the market. The investment banker who can serve a corporation in public financing of national scope must not only be honest and farsighted but must be financially powerful, with ample capital and credit, with strong connections, and with an organization which can provide a far-reaching distribution

of the securities in question. Securities of the better grade are sold today on a very low margin of profit, and the investment banking houses which are in a strong position today are for the most part those whose size, organization, and prestige enable them to do a considerable amount of underwriting, thus realizing the underwriter's profit. This trend to larger business units in the investment banking business is simply in accordance with the trend of business in general.

Financial Problems of Smaller Companies. The discussion to this point has assumed corporations of large size and with established earning records, whose securities may be expected to have a nationwide market. It should not be forgotten, however, that there are a large number of smaller corporations which enjoy excellent business opportunities, are ably managed, and have interesting futures. The farsighted investment banker is certainly not disposed either to despise or to neglect such companies. He is interested in becoming acquainted with the men who direct them, in keeping files of their statements, and in watching their progress from year to year. Such an investment banker is always glad to consult with the financial executive of any such smaller company concerning either his immediate financial problems or his long-time financial policy. The corporation which has not yet reached the point at which its net worth and earnings entitle it to use the national market in securing capital is of course dependent on its local bankers. It is understood, of course, that there is no business enterprise, large or small, which does not find the goodwill and confidence of its local bankers highly desirable, but the smaller concern is much more limited as to the market in which it may secure its funds. It is a mistake for any such company to make a premature attempt to do its financing away from home. The first step in developing a national credit, after local credit has been firmly established, is to open accounts with one or more strong and well-known banks in the great financial centers. The next step, in case the company has fairly sizable current borrowing requirements, may well be the sale of its commercial paper through some strong house which can give it a wide distribution. The establishment of the company's name as an acceptable credit risk among the bankers of the country is in itself a very valuable form of credit advertising. But whether the company has occasion to use the open market or not, it is a valuable thing for the financial manager to become well acquainted with the members of some strong investment banking organization, to keep them apprised of his company's progress, and to seek their advice on the broader aspects of his financial policy. He need have no fear that the investment banker will consider this a waste of his time. Such bankers are always interested in able management, wherever they may find it, since this is the most important single factor affecting the soundness of the securities which they offer their customers, and they know where there is able and ambitious management there is always a strong probability that the business will eventually become eligible for national financing.

Conclusion. In the foregoing chapter no attempt has been made to define procedures to be followed by the financial executives in prescribed cases. Other things being equal, any one of a number of variables may conceivably make an important difference in the type of financing that is desirable, the

kind of securities to be offered, the terms of the contract, or even the time when the financing is to be undertaken. Any piece of long-time financing that is attempted must be carefully designed by experts, with full consideration of all the factors that enter into the situation *at the time*. For this reason the writer has confined himself to a consideration of certain tendencies which have been apparent in the long-time financing of the postwar period. It is safe to say that every piece of financing undertaken at any time represents a carefully drawn plan designed to secure the required capital on terms which will be as favorable as possible to the issuing corporation in view of the existing market for corporate securities. And the experienced investment banker is typically the best judge of the receptivity of the market for a particular type of security at a given time. Under the present organization of our economic system, fluctuations occur in the level of earnings, for business in general, as well as for particular industries, and for this as well as for other reasons, the demand for corporate securities changes from time to time, not only in total amount, but also in the direction which it takes. Rails, utilities, industrials, banks, investment trusts—each group has its periods of investor popularity and its corresponding periods of disfavor. The same is true of the form of security issued. Bonds, debentures, serial notes, preferred stocks and common stocks, with all their variations, come and go in popularity with the investor. This continual shifting in the nature of the market for capital makes it highly desirable that the typical company should be capitalized and financed in such a conservative fashion that its executives can choose their own time to enter this market through an offering of its securities.

CHAPTER VI

SHORT-TERM BORROWING

BY MARY RODGERS LINDSAY, *Editor, Business Conditions and Forecasts,*
American Management Association

The capital required to meet the needs of any business enterprise may be provided through the sale of securities, it may be taken from the profits which have arisen out of the pursuit of the business, or it may be secured through short-term borrowing. At the time the enterprise is launched sufficient capital should be provided through the sale of stocks and bonds to cover not only such fixed requirements as land, buildings, and equipment but to meet the ordinary working needs of the business, such as the purchase of raw materials, labor, heat, and light. Permanent working capital should be provided through permanent financing.

As the business grows additional capital requirements can often be met out of the company's profits. If it is found, however, that these are not sufficient to cover an expanding volume of business which may require new buildings, land, and equipment and additional working capital, funds for such needs should be secured through the further sale of securities rather than through short-term borrowing.

Borrowing is advisable as a rule only for the purpose of meeting emergency or seasonal needs or of taking advantage of cash discounts. A more complete discussion of legitimate reasons for borrowing will be found in a succeeding paragraph.

Methods of Short-term Borrowing

Funds for short-term requirements may be secured in various ways. Among these, the following are methods commonly used by business and industrial concerns. A discussion of public utility and railroad borrowing is beyond the scope of this chapter.

1. Unsecured bank loans.
2. Sale of promissory notes on the open market.
3. Discounting trade and bankers' acceptances.
4. Loans secured by stock market collateral.
5. Commodity loans.
6. Assignment of receivables.
7. Installment financing.
8. Miscellaneous methods of short-term borrowing.

1. Unsecured Bank Loans. The most common method of short-term borrowing is through discounting the concern's promissory note or notes at one or more banks. These are unsecured time loans with a definite date

of maturity ranging from one month to one year although the maturity is usually from sixty to ninety days or four months. They are as a rule single-name paper, that is, they are the direct obligation of the company. These notes are occasionally though not as a rule endorsed or guaranteed by another party. If the firm's financial condition is sound and the character of its management is high this is the simplest and usually the most satisfactory method of covering short-term requirements.

Selection of the Bank. The selection of the bank is important. The size and financial strength of the bank must be considered. While the bank may be sound enough financially it may not be large enough to take care of all of the customer's requirements, in which case he must either select a larger bank or borrow from more than one bank.

It is usually desirable to select a bank which has specialized in or is familiar with the company's own line of business. Thus the bank will understand thoroughly all of the conditions surrounding the operation of the business and will therefore be better prepared to render service and to furnish funds when they are needed. The service which the bank is prepared to render ought to be investigated. Many banks have service departments which are able to give valuable advice on management problems of many kinds. As a financial adviser, the bank has often rendered outstanding assistance.

Two additional factors to be considered in choosing a bank are those of location and convenience. For the small company particularly, it is important to select a local bank. The local banks can render frequent advice, and can be relied upon to take a personal interest in the concern's welfare.

Information Required by the Bank. Before the bank is willing to discount a firm's promissory note it requires the company to present a complete financial statement and a profit and loss statement. Formerly, the usual test of financial soundness was that the company's ratio of current assets to current liabilities be in the proportion of two to one. The current ratio is unquestionably an important strength measurement in that it establishes the relation between debts maturing in the near future and the assets from which payment will be made. It is now customary, however, to supplement this with other ratios, such as: worth to debt, worth to fixed assets, merchandise to receivables, sales to receivables, sales to merchandise, sales to fixed assets, sales to net worth. While the current ratio is not in all instances the most important or controlling ratio, yet it always has a place of importance in the analysis of any financial statement. Theoretically, the banks desire that the current ratio be two to one, but in actual practice they may be willing to loan to a concern whose current ratio is as low as one and a half to one, or even less in some instances, dependent upon the circumstances. Many other questions covering the operation, management, and past profits of the business may be asked.¹ A complete audit of the company's business by a certified public accountant

¹ For a complete discussion of the information commonly required by banks, see E. E. Lincoln, "Applied Business Finance," pp. 383-392, McGraw-Hill Book Company, Inc., 1929; and Joseph M. Regan, "Financing a Business," pp. 143-159, LaSalle Extension University, 1921. For a thorough treatment of analytical technique in statement analysis, see A. Wall and R. W. Duning, "Ratio Analysis of Financial Statements," Harper & Brothers, 1928.

is required before the initial loan is made, and an annual audit thereafter. Semiannual or even quarterly statements of condition must also be furnished.

The Purpose of the Loan. The banker will sometimes wish, and is entitled, to know the purpose for which the proceeds of the loan are to be used. The bank will usually require that the loan be for short-term needs only. It is as a rule not to the bank's advantage to furnish, on short-term notes, funds for fixed capital requirements, such as land, buildings, and equipment. Bankers have upon occasions loaned funds on short-term notes for such permanent purposes. They have done so only when they have felt that the additions to property or plant would enable the concern to make increased profits through such expansion sufficient to repay the loan at its maturity. Too often, however, the bank has found itself compelled to make frequent renewals of such loans and it has become, therefore, in effect an investor in the enterprise rather than merely a short time creditor.

Theoretically, in the opinion of many writers, the loan ought to be self-liquidating if possible, that is, the transactions which the proceeds of the loan are to finance, ought to furnish before the loan matures the funds with which the promissory note is to be paid. The maturity of the loan ought to depend, therefore, theoretically upon the length of time which will be required for the specific transaction financed to be self-liquidating. In actual practice, however, the maturity of the loan is dependent upon the company's average rate of turnover rather than upon the length of time required for any specific transaction to be self-liquidating. The promissory notes which the company gives to its bank from time to time are related, therefore, to a number of transactions rather than to any specific transaction.

The Line of Credit. After estimating the short-term requirements of the company, the financial officer arranges for a line of credit at the bank. How extensive the line of credit can be depends upon the ratio of the company's current assets to current liabilities and other ratios, upon the annual turnover of stock, upon the terms of sale and purchase in the trade, upon the type of business, the commodities handled, the past and probable future profits of the company, and many other considerations. The line of credit indicates the maximum amount which the bank is willing to loan to the concern at any one time depending upon the credit rating and average bank balance maintained by the concern. As the company needs funds from time to time it negotiates loans to cover such needs; at other times the line of credit is unused and remains open only if the concern complies with the particular regulations of the bank with which it does business. Although it may be against the company's policy to borrow, it is good practice to keep bank lines open at all times, for if an emergency should arise, a loan may be arranged easily and at a favorable rate of interest to carry the concern until it may again be independent of outside funds.

As a basis of credit extension, the bank expects the borrowing concern to maintain on deposit with the bank an average balance equivalent to a certain percentage of the amount which has been borrowed. The usual deposit requirement is twenty per cent of the amount borrowed, although it ranges from ten to twenty-five per cent.¹

¹ For a discussion of the 20 per cent deposit requirement see E. E. Lincoln, "Applied Business Finance," pp. 406-409, McGraw-Hill Book Company, Inc., 1929.

Negotiating the Loan. The actual procedure in negotiating the loan is as follows: When the company finds that it will need a certain amount of funds for a short period of time, the financial officer of the company applies at the bank for a loan. If the concern's line of credit has been kept open as previously indicated, the bank agrees to extend a loan. The financial officer signs a short-term note for a specified amount. The bank then discounts this note by depositing to the credit of the concern an amount equivalent to the face value of the note minus the agreed upon rate of interest. This rate is dependent upon the prevailing open market rates, and upon the standing and credit rating of the borrowing company. Among the factors which affect the rate of interest are the following: the general state of business, that is, whether the country is passing through the stage of prosperity or depression within the business cycle; the time of year; the section of the country, for example, in the South, Middle West and Far West rates are higher; the duration of the loan; the nature of the risk; whether the borrower is an old customer of the bank of long standing or a new comer; and whether the concern is large or small. A large company is frequently granted preferential rates.

During the period of the loan the borrower is expected to keep on deposit an amount equivalent to a definite percentage of the total sum borrowed as previously mentioned. At maturity the note may be paid in full or if circumstances warrant or compel the bank may renew the loan. Renewals are often at a higher rate of interest, unless provision was made in the original contract that renewals of the loan be at the same rate.

The Periodic Clean-up of Loans. Theoretically, the banks expect their customers to make a periodic clean-up of loans, at least once annually. In actual practice few banks are strict in requiring customers to pay off all outstanding notes periodically. The banks are more strict with the small concern than with the large concern in regard to the annual clean-up of loans although they do not always insist that even the small concern make a periodic clean-up. The larger concerns usually find it easy to pay off notes due one bank by borrowing at another.

2. Sale of Promissory Notes on the Open Market. As an alternative to borrowing from the banks on unsecured promissory notes, larger and stronger business concerns often find it more convenient and less expensive to sell paper on the open market. The company's promissory notes are sold through the agency of commercial paper houses. These notes are, as a rule, unsecured and for the most part single name. They are occasionally endorsed or guaranteed by interested parties. The term given to such unsecured promissory notes is commercial paper. This is in the strictest meaning of the word in contradistinction to customers' loans made directly by the commercial banks. The notes are sometimes secured by collateral. Double-name trade paper is much less usual than single-name paper.

History of the Commercial Paper System. The commercial paper system in its present form dates back to the eighties. It had its greatest development during the years from 1907 to 1920, the latter being the peak year. From 1920 to 1929 the amount of commercial paper decreased until in September, 1929, the amount outstanding was less than one-fourth as great as in the same month of 1920. During 1930, there was a marked increase in the amount of

paper sold on the open market. In September, 1930, the amount outstanding was almost twice that in September, 1929. Commercial paper totaled \$513,000,000 in September, 1930, in contrast to \$265,000,000 in September, 1929, and \$1,064,000,000 in September, 1920.¹ There are at present in the United States about twenty-five representative dealers of whom not more than fourteen or fifteen are national in scope. The number of business houses selling paper on the open market is relatively small. In 1920, 4,395 companies used this method of short-term borrowing. The number had decreased to about 1,200 or 1,500 in 1928. Exact figures are lacking for 1930 although it is known that there was a definite increase in the number of firms offering their paper on the open market. This is in keeping with the increase in the total amount of commercial paper outstanding. According to the National Credit Office of New York City, the following are the prominent industries which used the open market in 1928, listed in the order of their importance based upon the number of concerns within the industry which employed open-market financing during that year: *textiles* (manufacturers of cotton, woolen, and worsted goods, hosiery manufacturers, manufacturers of men's wear and of work clothing, wholesalers of dry goods, department stores, factors); *food stuffs* (flour millers, meat packers, and wholesale grocers); *metals* (manufacturers and wholesalers of light and heavy hardware, and of light and heavy machines, manufacturers of stoves and ranges); *leather* (manufacturers of shoes, tanners of upper leather); *lumber* (manufacturers and retailer of furniture and of lumber); and *miscellaneous* (auto finance, wholesale and retail; wholesale drugs).

Prior to 1913 the commercial paper system tended to serve as the basis of the only open discount market in the United States. Since the founding of the Federal Reserve System the latter has become the chief agency for performing this service because of its facilities for rediscounting commercial paper.

Types of Concerns Using the Open Market. Only the larger and stronger concerns are able to borrow on the open market. Formerly the better commercial paper dealers would not sell paper for concerns whose net worth was less than \$300,000 or \$400,000; now the minimum net worth is about \$200,000. The majority of firms who use the open market have a net worth of \$500,000 or more. Certain types of concerns are unable to sell their paper on the open market. Dealers refuse to do business with the following types: new or little known concerns no matter how strong they may be financially; producers or distributors of "styled" lines, and luxuries, inasmuch as these are poor risks because of the rapid change in consumer preference; those concerns which sell on time, or whose merchandise turnover is slow; those companies manufacturing or distributing products which are subject to rapid price fluctuations or for which the demand cannot be estimated.

The procedure of selling paper on the open market is as follows: The financial officer of the concern selects a commercial paper house whose reputation and good standing is definitely known, preferably one of the fourteen or fifteen

¹ These figures are based upon commercial paper outstanding, maturing within seven months, as reported to the Federal Reserve Bank of New York by twenty-five dealers.

whose business is national in scope. He then makes application for a loan. The dealer makes an exhaustive examination into the condition of the applying concern. This includes a full and properly audited statement of condition. Liquidity of current assets is also important inasmuch as there is no personal element in the open market, and notes must be paid at maturity. A comparative record of earnings covering several years' time must be presented. The broker makes use of credit reporting agencies; he makes inquiry not only at the customer's bank or banks but at other banks in the community in which the concern is located; he also makes inquiries of the company's creditors and customers, as well as within the trade.¹ The character and ability of the management is a factor which is given important consideration. The loan must be for strictly commercial purposes and must ordinarily be self-liquidating.

In order to find a market for the paper at small banks as well as at large the loan is broken up into a number of promissory notes of varying denominations ranging from \$2,500, to \$10,000, the common amounts being from \$5,000 to \$10,000. The notes are as a rule made payable to the order of the borrowing concern, at a designated bank, signed by the borrower, and endorsed by him in blank. Usually the notes are signed by the duly appointed borrowing officer of the concern although they are occasionally endorsed by officers who are known to possess considerable personal property. If the concern needs the funds immediately, the commercial paper house buys the block of notes outright, in which case the borrower receives their discounted value, less the dealer's commission. The dealer's commission is one-fourth of 1 per cent irrespective of maturity. The rate of interest at which the paper is discounted is in this case that prevailing at the time in the open market. Most paper has a maturity of six months, although the range is from two to ten months.

If the concern is not in immediate need of the proceeds of the loan the dealer will arrange for the sale of the paper within a period of several weeks' time or even a month or so. When the notes are actually sold the customer will receive the proceeds of the loan discounted at the rate agreed upon by the broker and buyer or buyers, less the broker's commission. In case the broker buys the paper outright and there is a change in open market interest rate between the time the broker buys and sells the paper, the broker gains or loses accordingly. If he merely acts as the concern's agent he then receives his commission alone and there is no possibility of profit through a change in the interest rate.

The commercial paper house sends a notice of its offerings to its list of banks and other institutions which customarily buy paper on the open market. The house sends to the prospective purchasers a full and detailed description of the results of its own investigation of the borrowing concern, including a financial statement of condition and references of various kinds. The buying organization, usually a bank, is given a ten-day option during

¹ For an illustration of the type of confidential credit information requested by one of the large commercial paper houses, see E. F. Lincoln, "Applied Business Finance," pp. 432-434, McGraw-Hill Book Company, Inc., 1929.

which time it also makes a thorough investigation of the borrowing company through financial reporting agencies and other bankers as well as through the trade. If during this period the paper is found to be unsatisfactory the bank may return it to the commercial paper dealer and receive again the principal sum plus interest. Otherwise, it keeps the paper and presents it at maturity for payment at the designated place.

While the commercial paper dealer does not guarantee the notes which he offers for sale, yet his reputation is at stake and some of the better houses have been known to make good any losses incurred on commercial paper bought through them. The losses on commercial paper, however, are very small. According to studies conducted by the National Credit Office, in no single year from 1922 to 1925 was the loss to banks on commercial paper more than one-tenth of 1 per cent. In 1922 the loss was .00013, .00023 in 1923, .00105 in 1924, .00087 in 1925. The average rate of loss on bond investments of banks during the same four years was about seventeen times the rate of loss on commercial paper.

Advantages and Disadvantages of Borrowing on the Open Market. The open market has been found particularly useful by those large concerns whose own local banks have been unable to supply all of their credit needs, due to the fact that although the borrowing company may be legitimately entitled to additional funds the bank may be prevented by legal limitations and other reasons from loaning funds enough to cover the concerns' short-term requirements. When a large business is located in a small community frequently the local bank cannot supply sufficient funds. The concern may in this case find open market borrowing particularly convenient. It may of course have recourse to banks in large near-by cities but even so the open market has certain distinct advantages. The open market rate of interest is usually, though not always, lower than the rate which the concern would be required to pay at the banks. There is, too, a certain prestige which is attached to this method of financing. Only those concerns which are financially sound and of the highest character can pass the rigid credit examination given by both commercial paper houses and the purchasers of commercial paper. Through borrowing on the open market the firm is able to keep its local bank lines open for emergencies. As a matter of fact, however, it is essential that the concern which is borrowing on the open market maintain credit lines in its local banks sufficient to cover its open market borrowing. Inasmuch as notes sold on the open market must be paid at their maturity the openmarket borrower must maintain his banking connections so that, in case an unforeseen emergency should arise, he may borrow from his banks to pay his notes when they fall due, if he is unable to arrange for the sale of another block of notes on the open market. This means that, as in the case of bank borrowing, the concern ought to keep on deposit in its bank or banks as a safeguard balances equivalent to 20 per cent of the amount which is being borrowed on the open market.

There are, too, certain disadvantages to open market borrowing. The publicity which is attached to open market borrowing is not always pleasant in nature. The borrower must stand ready to answer all kinds of questions covering his business. The firms from which he buys, his competitors, his

own bank, and other banks are solicited for information relating to his credit standing and position within his trade. If the concern's paper is refused, untold injury results to its reputation and credit standing.¹

Despite the striking increase during 1930 in the amount of commercial paper sold on the open market following the stock market collapse in the autumn of 1929, many authorities believe that the commercial paper house will gradually disappear. If this proves to be true, it is to be regretted inasmuch as the commercial paper system has certain outstanding advantages for the country as a whole. It tends to secure a better distribution of the funds of the country and thus to equalize interest rates in different sections of the country. At present, rates in the Middle West, in the South, and in the Far West are considerably higher than in the East. The commercial paper system supplies the banks with outlets for their surplus funds and greater safety through increased liquidity of their portfolios. Not only are bank losses on commercial paper less than on bond investments but the rate of yield is also greater than on bonds. There is to be considered, too, the fact that the commercial paper system furnishes a sort of wholesome competition to the banking system, a factor which is not to be minimized. It is, therefore, to be hoped that the commercial paper system will not disappear as appeared probable in the years from 1920 to 1929.

3. The Trade Acceptance. Within certain industries the trade acceptance is used as a means of short-term financing. Among these are the following: fur, jewelry, electrical equipment, textile, raw silk trade (by members of the Raw Silk Trade Council), rubber tire manufacturing, agricultural implements, and lumber. The trade acceptance is used primarily by manufacturers, inasmuch as leading wholesalers have as a rule been opposed to it. It is generally used where terms are medium to long, and bills are of considerable size. Many business concerns use the trade acceptance as a collection instrument alone, that is, for slow-paying customers, while in some lines such as agricultural implements and lumber, and in the raw silk trade, it is used instead of the open account system for all customers who take net terms. In the rubber tire manufacturing industry it is used for shipments bearing the spring dating, in order to give to the seller a definite instrument as evidence of the transaction.

The trade acceptance has been defined as "a time draft drawn by the seller of merchandise on the buyer for the purchase price of the goods and accepted by the buyer, payable on a certain date, at a certain place designated on its face."

The customary procedure in connection with the use of the trade acceptance is as follows: When rendering an invoice for the purchase of merchandise, if the amount is reasonably large, the seller will accompany the invoice with a trade acceptance form filled out for the amount due, or if the buyer purchases several bills of small amounts during the month, the seller will accompany the monthly statement with a trade acceptance form filled out for the total amount due. The buyer has the option of either paying the bill, deducting

¹ For a discussion of the advantages and disadvantages of commercial paper to both the borrower and buyer, see R. G. Rodkey, "The Banking Process," pp. 141-153, The Macmillan Company, 1928.

the cash discount if such is allowed, or he may "accept" the trade acceptance by writing across its face the date and the words "accepted payable at . . ." (filling in the bank or designated place), signing it, and returning it to the seller.

The seller then either holds the acceptance in his portfolio until a short time before it is due, when he will forward it through his bank to the bank designated for acceptance or to the acceptor at his own place of business or other designated place; or if the seller finds himself in need of funds, instead of borrowing from his bank on his unsecured promissory note, he may discount a number of trade acceptances at his bank or sell them in the open market through brokers or commercial paper houses. He is then able to borrow upon capital which is at present tied up in open book accounts.

Legally, unless a different place is designated on its face, the place of payment of a trade acceptance is at the office of the acceptor, that is, the buyer of the goods.

*History of the Trade Acceptance.*¹ The trade acceptance was used considerably in this country before the civil war. During the period of the civil war, because of the uncertain trend of prices as the result of excessive issues of greenbacks there developed the policy of doing business on a cash basis. The practice of selling goods by sample, instead of by selection from stock on hand, developed during the eighties. The so-called doctrine of "implied warranties" originated as a result by which the risk and responsibility was placed upon the seller. Thus the use of the open account superseded the old method of drafts; this in turn caused sellers to offer cash discounts as a reward for prompt payment. Little by little, the cash discount open account system developed into its present form and today is the prevailing system in the majority of industries in the United States.

Since the passage of the Federal Reserve Act, the use of the trade acceptance in the United States has passed through three stages: (1) a period of gradual increase from 1914 until the autumn of 1917, (2) the war period, during which an active effort was made to increase the use of the trade acceptance. The Federal Reserve Act permitted the reserve banks to purchase bills of exchange or trade acceptances in the open market, as well as to rediscount them; promissory notes can only be rediscounted. Both the Federal Reserve Board and the National Association of Credit Men sponsored the use of trade acceptances and a special organization called the American Trade Acceptance Council was formed to wage an active campaign to increase their use. (3) A period of decline extending from 1919 to the present time. At the beginning of this period attention was called to the many abuses in trade acceptance practice. During this stage the American Trade Acceptance Council's name was changed to the American Acceptance Council and its attention was shifted to the banker's acceptance.

There has been since 1919 a gradual decrease in the use of trade acceptances. The exact extent of their use is difficult to estimate, inasmuch as many concerns use them as a collection instrument alone, that is, they do not discount

¹ The discussion of the history of the trade acceptance has been summarized largely from H. P. Willis and W. H. Steiner, "Federal Reserve Banking Practice," pp. 220-222, D. Appleton & Company, 1926.

them but merely hold them within their portfolios until they mature at which time they are presented to the acceptor for payment.

The banks have objected to the use of trade acceptances as a means of raising short time funds, because this entails the handling of many pieces of paper of small and uneven denominations. Naturally, the labor and expense required is greater than if the borrower were to give one promissory note to cover his entire needs. As a rule the banks have preferred, therefore, to loan on unsecured promissory note. The banks have found, too, that the risk involved must be investigated almost as thoroughly in case of trade acceptances as in the case of unsecured promissory notes.

Abuses of the Trade Acceptance. Among the abuses which have led to a gradual decrease in the use of the trade acceptance are the following:

The trade acceptance has been used in certain lines to collect overdue accounts, and has not been drawn at the time of the actual transaction. The practice is frowned upon by both advocates and opponents of the trade acceptance. It is generally agreed that a trade acceptance ought to be given at the time of sale, not after the transaction. To avoid this abuse, the Raw Silk Trade Council has provided a place on its standardized trade acceptance form for the date of the invoice.

A second abuse is that upon occasions two parties have agreed to exchange trade acceptances when no actual transfer of goods has taken place. A large New York bank recently found to its dismay that two parties had agreed to give trade acceptances, the one drawing an acceptance against the other and the other accepting it. The first party carried the false acceptances to the bank for discount. The second party at first paid a few acceptances upon their maturity to avoid suspicion. More and more acceptances were presented at the bank for discount. Finally one party defaulted and the other followed suit. The bank brought action and won its case, but in doing so it learned a valuable lesson, that is, the importance of investigating both the transaction and the two parties involved before discounting a trade acceptance.

Another abuse which has arisen is that successive trade acceptances have been used on the same goods in various stages of distribution. This, of course, leads to inflation and endangers the entire credit structure.¹

The Banker's Acceptance. The banker's acceptance is used primarily in financing export and import trade and in financing domestic shipments where the buyer and seller are unknown to each other, when because of distance or other reasons the seller finds it difficult to investigate the credit standing of the buyer. One of the common domestic uses is to assist in the orderly marketing of crops. It has been estimated that approximately 75 per cent

¹ For a searching analysis of the case of the trade acceptance vs. the cash discount system, see H. P. Willis and W. H. Steiner, "Federal Reserve Banking Practice," pp. 222-226; and for a discussion of the arguments for and against the use of the trade acceptance see E. E. Lincoln, "Applied Business Finance," pp. 461-473 and 476-479. The advantages of the trade acceptance to the buyer, to the seller, to the consumer, and to the banker are set forth in the booklet by Robert H. Treman, "Trade Acceptances," pp. 34-60, American Acceptance Council, 1930.

of the banker's acceptances are used in financing foreign trade while only 25 per cent are used in domestic transactions.

The bank acceptance is "merely a time draft drawn against a bank and accepted by the latter by stamping the word 'accepted,' the date, and the signature of an officer across the face of the draft." The prospective buyer of goods arranges with his bank to extend a line of credit sufficient to cover the anticipated transaction. The bank notifies the seller that an acceptance credit not exceeding a certain amount to cover the expected sale has been opened by the buyer. The seller draws his draft normally accompanied by bill of lading, and also by consular invoice in case of foreign trade, by insurance policies and the like; this he discounts at his bank at the prevailing rate of interest; his bank presents it at the bank which has authorized the acceptance, which in turn accepts the draft. After the goods arrive, the buyer must in order to take possession of them secure the bill of lading and other documents. To do this he must sign a trust receipt at the acceptor bank. Before the acceptance matures the buyer deposits funds in the bank sufficient to cover the acceptance. The banker's commission is paid as a rule at the time the draft is accepted. When banker's acceptances are used to finance readily marketable staples in storage, they are secured by warehouse receipts.

When because of legal limitations the local bank is not in a position to advance all the funds which its customer needs, the borrower may be able to obtain additional funds through the bank if the latter will accept a time draft drawn against the bank by the customer. The bank then sells this on the open market and credits the customer's account with the proceeds.

The distribution of acceptances is usually made through discount houses, through finance companies, and even through some of the commercial paper houses.

4. Loans Secured by Stock Market Collateral. During the stock market boom preceding the collapse in October, 1929, many concerns invested their surplus funds in good stocks considering that this was not only a legitimate use to make of surplus but also hoping to profit through a rise in the value of the securities. If a business concern has stocks or bonds within its portfolios, it can often persuade its bank to lend on these as collateral funds in excess of the amount which the financial standing of the company would ordinarily entitle it to receive. The bank will lend up to within a certain margin to cover any possibility of a change in the market price of the collateral or the necessity of selling the securities, should the borrower fail to pay the loan at its maturity.

This method of raising funds for a short period of time has recently proved popular, not only because as a rule the rate of interest on such loans is slightly lower than on unsecured promissory notes but also because concerns which had invested part of their surplus in securities during the stock market boom felt it advisable to hold these securities for the time being rather than to sell them at unfavorable prices. In preference to selling a block of these at a loss for the purpose of securing again part of the surplus so invested companies borrowed on such securities as collateral at their banks.

5. Commodity Loans. While business concerns customarily obtain their short-term funds by borrowing from banks on unsecured promissory notes,

at times such funds are obtained through loans against commodity collateral. By means of such loans the business concern can obtain a relatively greater advance than its own financial standing and credit rating would entitle it to obtain on its unsecured promissory note.

As a rule only non-perishable staples with a ready market are desirable as collateral from the bank's point of view. Such collateral is confined, therefore, largely to raw materials rather than manufactured goods. Included in this classification are: grain, cotton, wool, silk, metals, coal, oil, hides, leather, building materials, sugar, coffee, tea, tobacco, and the like.

The goods are stored in public warehouses from which the owner obtains warehouse receipts covering the items which he has deposited. The holder of the warehouse receipts may then borrow from his bank on his promissory note secured by the warehouse receipts up to within 10 to 25 per cent of the full market value of the goods. If such goods are being held for legitimate business reasons, rather than for speculative purposes, promissory notes secured by warehouse receipts covering the storage are eligible for rediscount. Paper, too, secured by warehouse receipts covering staple perishable food products such as butter, cheese, eggs, poultry, etc., carried for seasonable periods in cold storage is also eligible for rediscount if offered with the endorsement of a member bank at the usual rate for ninety-day commercial paper. Banker's acceptances are also employed at times to finance such staples in storage. These must of course be secured by warehouse receipts and are therefore referred to as "warehouse acceptances."

Banks have found that the moral risk in connection with commodity loans is almost as great as on unsecured promissory notes. This is illustrated by a recent example. In 1925, a chain of food stores borrowed on warehouse receipts covering the storage of sugar in a warehouse located in Brooklyn. An officer of a leading bank who had granted a loan on these warehouse receipts as security became suspicious and decided to investigate the existence of the collateral. It was found that the sugar was stored in the warehouse to the amount which the receipts indicated but when the firm failed a short time later it was discovered that duplicate warehouse receipts covering the same sugar had been used to borrow from four other banks. Naturally, the banks were the losers.

Borrowing on bills of lading against shipments is another means of securing funds for a short period of time. The usual procedure has been described in the section on Banker's Acceptances.

Specific merchandise in the concern's possession may also at times be used as collateral for loans. A chattel mortgage covering all of the borrower's movable possessions is sometimes given, but such a procedure is followed only as a last resort and as a rule indicates that the borrower is approaching bankruptcy. The "lease" and "conditional sales" contract are employed under certain conditions. It is rarely possible to borrow from the commercial bank on specific merchandise within a concern's possession. Such loans must generally be obtained from finance companies at a considerably higher rate of interest than the bank would charge on ordinary commercial loans.

6. Assignment of Accounts Receivable. Occasionally, in order to secure the necessary funds with which to postpone or forestall financial insolvency,

companies sell their open book accounts. This is referred to as "assigning," "hypothecating," or "pledging" accounts receivable. Loans of this type can seldom be obtained from the ordinary commercial bank but must be secured from finance companies at a higher charge than the customary rate of interest.

Either the notification or non-notification plan may be employed by the finance company. Under the notification plan, the debtor receives notice that his account has been sold or assigned and that he is to make payment to the finance company; under the non-notification plan the debtor is not notified but continues to make payment to the seller. The non-notification basis is naturally preferred by the borrower, but the notification plan is preferable from the point of view of the lender and of the community as a whole.¹ At the present time, the non-notification plan is the more usual one due to its convenience. A larger rate is charged by the finance company under this plan than under the notification plan because of the greater amount of credit and supervisory as well as bookkeeping work involved. Under either plan the borrowing company can usually secure advances not exceeding 75 to 80 per cent of the face value of its accounts receivable. The larger finance companies charge one-twenty-fifth of 1 per cent per day on the net face value of the receivables and in addition \$5 per \$1,000 on the first \$100,000 of receivables during any year.

7. Financing Installment Sales. Inasmuch as installment financing covering sales of articles other than automobiles presents much the same general problems as automobile finance and inasmuch as by far the greater part of installment financing is in connection with the sale of automobiles, the discussion will be confined to problems arising in connection with the distribution and sale of automobiles on the installment basis. Since commercial banks have never attempted to handle installment paper, borrowing of this type must be obtained exclusively through finance companies. The manufacturer's relation to the distributor or dealer is very similar to that in other types of business. The manufacturer sells his goods either to independent dealers or to his own agents; to the latter he makes concessions in terms and prices. In all cases it is customary for the manufacturer to demand payment in cash. A sight draft with bill of lading attached is drawn on the dealer or distributor. Before the latter can receive the automobiles for which he has contracted, he must secure the bill of lading; to obtain the bill of lading he must pay the draft. To enable the dealer to obtain possession of the automobiles the finance company loans the dealer up to 90 per cent of the total invoice price, less the finance charge which includes interest and insurance on the cars. The dealer gives his promissory note secured by warehouse receipts if the cars are stored in a warehouse or secured by the cars which are on the dealer's floor. The dealer has possession of the cars under a trust receipt but the title remains in the hands of the finance company. This is the so-called wholesale plan.

Since many of the dealers also sell at retail the wholesale plan is closely bound up with the retail sales plan. Under the latter plan the consumer-

¹ On this point see H. P. Willis and W. H. Steiner, "Federal Reserve Banking Practice," pp. 237-239.

purchaser makes a down payment usually amounting to one-third of the retail price if the car is new, or to one-half if the car is secondhand. The balance due is paid in monthly installments ranging from six to twelve months, ten months being the common period. The customer gives his note covering the amount due after the initial payment has been made plus the charges of the finance company. These include both interest and insurance and as a rule total in all about 15 per cent. Under a conditional bill of sale, chattel mortgage, or lease agreement, the buyer obtains possession of the car during the period that the note is being paid but the title remains in the hands of the finance company. Formerly the finance company collected from the dealer to whom the purchaser paid the installments as they fell due. Now it is more usual for the finance company to collect directly from the purchaser.¹

8. Miscellaneous Methods. Other methods of raising short-term funds which are occasionally employed are the following: loans secured by real estate and other property, loans on insurance policies, and character loans. Character loans are, however, as a rule for personal purposes; they may be obtained through such organizations as the Morris Plan banks and some of the large metropolitan banks. Such notes usually require two co-endorsers.

Estimating Short-term Requirements

It is good business policy to borrow only when by so doing profit will accrue to the firm. No concern can afford to borrow, at a rate of 10 per cent, funds which when used will bring to the company net profits of only 8 or 9 per cent. It is the duty, then, of the financial officer, when estimating probable short-term requirements to ascertain in advance whether the funds which he contemplates borrowing will, when used, bring to the company a net return considerably above the rate of interest which must be paid on the loan.

Legitimate Reasons for Short-term Borrowing. Among the reasons for short-term borrowing which are recognized as being legitimate are the following: It is considered good policy to borrow funds to purchase raw materials and labor with which to manufacture those goods for which the manufacturing concern has orders on hand, if the concern does not have funds sufficient to cover these needs. Such borrowing should be only for such period of time as that which intervenes between the time when the orders are received and the time when the invoices are paid. This period varies according to the terms of sale of the individual company which in turn depend upon the terms of sale which prevail within the industry. The usual range is from sixty to ninety days. The maturity of the loan should, therefore, correspond. In this instance as well as in all other cases of short-term borrowing it is essential to estimate the profit which will be derived from the borrowing in order to be assured that a net return will accrue to the company.

A second purpose for which it is considered legitimate to borrow funds is to cover seasonal peaks. It is rarely profitable for a company to secure sufficient permanent working capital through the issue and sale of its securities to take care of all of its seasonal needs. To pay dividends on stocks or interest

¹ For a full discussion of methods of installment financing, see E. R. A. Seligman, "The Economics of Instalment Selling," vol. 1, pp. 55-91, Harper & Brothers, 1927.

on bonds in order to have funds on hand throughout the year when such funds are to be used only for from three to six months within the year is on the face of the proposition poor business practice. It is usually to the company's advantage to pay interest on bank loans covering the duration of its seasonal peak or peaks rather than to have on hand during the entire year permanent working capital in sufficient volume to meet seasonal as well as all-year-round needs.

A third legitimate reason for borrowing is to *take cash discounts* which are offered for prompt payment of the company's bills. If the terms of sale are 2 per cent ten days net thirty days, by paying the bill in ten days instead of thirty days and taking the cash discount of 2 per cent the rate of saving for the remaining twenty days is equivalent to 36 per cent per annum. When net terms are thirty days it scarcely pays a concern to obtain a bank loan in order to take advantage of a cash discount of only $\frac{1}{2}$ per cent ten days but if the cash discount is 1 or 2 per cent then to borrow to take advantage of the discount is profitable.

Fourthly, it is often necessary for the company to resort to borrowing for *emergency needs*. In order to safeguard the company's credit standing or reputation, such borrowing is not only legitimate but pays returns over a period of years.

Budget of Short-term Requirements. To be reasonably sure of obtaining funds when they are needed, it is necessary to arrange for them in advance. In order to determine how large a line of credit is needed at the bank, or what amount of funds must be secured from other sources, some kind of an estimate or budget of the financial requirements of the period is absolutely essential to any well-managed business. It is important, therefore, to have well formulated plans for the entire business. The financial estimate is dependent upon the general budget covering all operations of the concern. The financial officer who is responsible for securing funds, whether he be the comptroller, the treasurer, or the vice president in charge of finance, must work hand in hand with the officer in charge of the general budget. The financial officer must determine certain safety points beyond which it is not advisable to borrow. If the budget estimates would require the borrowing of funds exceeding these safety points, it is the financial officer's duty to inform the director of the budget, and he in turn must make a general revision downward. The financial officer must also determine the amount of bank credit to be held in reserve for contingencies which are not included in the budget proper.

As soon as the amount of necessary borrowing has been carefully estimated it is the financial officer's duty to arrange lines of credit at the bank or banks with which the concern customarily does business, or, if he deems it advisable to secure the loan from another source, he will make arrangements with the commercial paper house, the finance company, or other source of funds as the case may be.

Selecting the Method of Short-term Borrowing. The majority of concerns find borrowing from their own bank or banks on unsecured promissory notes the most convenient and as a whole the most satisfactory method of obtaining short-term funds. Borrowing from the bank on stock market or commodity

collateral, if a concern has such specific collateral within its possession, as a rule carries with it the advantages of a lower rate and the possibility of more extensive accommodation than a concern's credit rating would ordinarily entitle it to receive on its unsecured promissory note. The better concerns can, however, usually borrow at about as low a rate on unsecured promissory notes. The smaller business concern finds it expedient and wise to stick to one bank. The larger, financially sound companies usually make a practice of borrowing from several rather than from a single bank, inasmuch as one bank can rarely offer sufficient accommodation due to legal limitations. Such concerns thus find it easy to make a periodic clean-up of their loans at one bank by borrowing from another.

For the welfare of any company, large or small, there are certain rules to be observed relative to bank borrowing. All details of the company's short term requirements should be carefully discussed with the company's bankers, and lines of credit should be arranged in advance. Absolute frankness and fair dealing is a policy which pays under all conditions. The bank's requirements in regard to the supplying of financial statements should be rigidly observed at all times. It is now customary to require semiannual and even quarterly statements of condition. These should be supplied voluntarily as a matter of good policy before the bank's credit department finds it necessary to request such statements.

It is well for the company's financial officer to consult with his banker or bankers frequently relative to the state of the company's business and its future. The bank's service department can in many instances render invaluable advice which will save the company much money and wasted effort. It is particularly advisable that the financial officer of the small business concern take his banker into his utmost confidence and consult him often as a matter of policy. Larger business concerns have in many instances found it beneficial to the company's welfare to consult a financial expert or firm of experts before undertaking any new project which would require additional financing either of a temporary or permanent nature.

To keep bank lines open to the extent of having on deposit at all times 20 per cent of the possible future requirements of the concern is a policy, which, at first glance, might appear to be expensive because of the fact that little or no interest is paid on such deposits, yet in the long run it has proved to be to the detriment of business concerns if such banking connections were not rigidly maintained. Concerns which have maintained cordial and satisfactory relationships with their bankers whether or no they were borrowing have found that in emergency cases the bankers have been willing to come to their rescue by loaning funds in excess of the amount which the financial condition of the firm would ordinarily warrant.

For the vast majority of firms, then, borrowing directly from the banks is the usual method of short-term financing, and the most satisfactory, whether such borrowing be through the medium of unsecured, one- or two-name promissory notes, or promissory notes secured by stock market or commodity collateral.

For the larger concerns, borrowing on the open market through the agency of the commercial paper house is often an expedient and very satisfactory

method of securing short-term funds. It has the obvious advantage of enabling the concern to borrow at a lower rate of interest and at the same time to keep its bank lines open for emergencies. A new issue of commercial paper can often be floated shortly before promissory notes sold on the open market fall due, in order to provide the funds with which to pay the notes as they mature. As a matter of caution, however, it is well to keep bank lines open sufficient to cover all open-market borrowing, so that if, due to some unexpected circumstance, the concern is unable to meet its obligations upon their maturity the concern can secure from its banks sufficient funds to enable it to pay its promissory notes when they fall due, thus conserving its credit standing and reputation.

If the smaller company's standing is not sufficient to enable it to obtain funds from its bank to cover its requirements, it has recourse to the finance company. The finance company loans funds against such collateral as commodities in storage or in the process of manufacture, or upon the pledging of its accounts receivable. Because of the risk in connection with the former and because of both the risk and of the detailed accounting and other labor entailed in connection with the latter, the finance company charges a considerable higher rate than the bank rate for such accommodation. Banks rarely loan on accounts receivable and then they prefer, naturally, the notification method as previously described. The assignment of accounts receivable is a means of financing only to be used in case of a really serious emergency. Such a procedure is detrimental to the credit standing of the company. Either of these methods of borrowing from the finance company are too expensive to be profitable under ordinary circumstances. They are, however, possible methods of securing additional funds when, in cases of dire necessity, a concern is unable to obtain from its bank funds sufficient to cover its pressing obligations.

There are certain specialized methods of financing suited to particular cases. The use of banker's acceptances is, for example, adapted to the financing of foreign trade, both exports and imports. There are certain industries, among them, the fur, jewelry, and textile industries, which have found the discounting of trade acceptances a satisfactory method of short-term financing. Installment financing requires specialized procedure and is handled exclusively by finance companies organized for this purpose, as has been previously discussed. But with the exception of these special instances bank borrowing on unsecured promissory notes is by far the most usual method of obtaining short-term funds.

Summary. During the long period of almost unbroken prosperity from 1924 until the autumn of 1929, business concerns accumulated cash balances. Companies took advantage of the ease with which new stock issues could be floated to obtain through the sale of securities sufficient funds not only to cover all working requirements but to provide surpluses for contingency needs as well. Part of the ample profits which were earned during this period were set aside by many companies as reserves for emergency needs instead of being distributed as dividends. The ironing out of seasonal peaks in some industries through carefully planned all-year-round production tended to eliminate the necessity of borrowing to cover seasonal requirements. During

this period, then, there was a tendency for business concerns to put themselves into a strong enough condition financially so that they were increasingly independent of outside funds for short-time purposes. As a net result there was a decided decrease in borrowing for short-term purposes. The striking decline in the amount of commercial paper sold on the open market during these years is not merely proof of the trend toward borrowing directly from the banks, as has often been thought, but proof also of a decrease in short-term borrowing by the larger corporations.

After the stock market collapse in the autumn of 1929, however, companies found it increasingly difficult to secure additional funds through floating new security issues. Stocks were no longer so popular as during the bull market, for the public had learned that participation in ownership might mean loss as well as gain. As surpluses accumulated during the long period of prosperity were gradually used up for contingencies and for working requirements during the depression which followed, corporations found it necessary again to resort to borrowing, either directly from the banks or through the agency of the commercial paper houses. The sudden increase during 1930 in the total amount of commercial paper sold on the open market was indicative of such a change.

CHAPTER VII

CONSOLIDATIONS AND MERGERS

TYPES OF CONSOLIDATIONS AND MERGERS

By DWIGHT T. FARNHAM, *Manager, Industrial Department, Peat, Marwick, Mitchell & Co.*

This is an attempt to classify the various corporate and economic types of combinations in America and Europe. To accomplish this it has been necessary to trace, to a certain extent, the historical and legal development of the various types in each country and to discuss the economic changes responsible for this development. An attempt has also been made to clarify the terminology which has become badly confused and to make clear the relation of the movement to certain contributing factors.

Corporate Types of Combinations. There are three principal corporate classes of combinations:

1. Those based upon the exchange or purchase of stocks, such as holding companies, consolidations, and mergers.

2. Those based upon contractual relations such as cartels, trade associations, etc.

3. Those based upon common interest such as that occasioned by stockholders or banking interests common to two or more companies, or by group consciousness which leads a class, a community or a country to cooperate for their own interest, against other groups.

Combinations also exist which contain all three of the elements described.

Class 1. While the terms "holding company," "consolidation," and "merger" are loosely used to describe almost any sort of industrial, financial or commercial combination involving the purchase or exchange of securities, each type has a distinct technical significance from a legal, financial, and accounting standpoint. Although lines of demarcation are not always carefully drawn and although one combination may include elements of one or more types, nevertheless there is a distinct difference from a corporate standpoint, as will be noted from the paragraphs which follow:

Holding Company. The holding company, sometimes incorrectly referred to as a "trust," usually acquires its holdings in other companies by purchasing their stock. In many cases it does not own all the stock of its subsidiaries, but in most cases these subsidiaries retain their original identities.

Consolidation. The consolidation is usually effected by creating a new company which buys out the business of the old ones, taking over their assets and assuming their liabilities.

Merger. The merger is usually effected by one company purchasing, on a basis of net worth and earning power, one or more other companies, which thereupon cease to exist as legal entities.

In many of these cases the former stockholders may be compensated in cash, in stock, or in a combination of both, and may or may not become identified with the new management. When compensation takes the form of cash, it is quite usual to secure this cash by means of a public issue of securities which are distributed by investment bankers. Compensation is frequently graduated, cash, bonds or preference stock being paid for liquid assets, preference stock for fixed assets and common stock for goodwill based upon earning power.

Class 2. Cartels. Other types of combinations based principally upon contractual relations of a more readily terminable nature may be grouped under the general heading of cartels. While this term is used in Germany to denote "a voluntary combination of business enterprises engaged in the same line of business, and each retaining its independence, for the purpose of establishing monopolistic control of the market," it may equally well apply to a large variety of corporate, contractual and general associations of various sorts in this country, if the statement of purpose is modified to conform with present legal requirements.

In Germany, where organization is most complete, cartels fall into two general classes from a legal standpoint, the *trade association*, without legal entity, from which any member may withdraw at any time, differing little from the "gentlemen's agreement" and the *registered association*, possessing legal responsibility and entering into definite contractual relations with its members covering a stated period. These two classes accomplish their objectives by various means and may be divided into general types as follows:

1. *Price cartels*, which fix and regulate prices.
2. *Trade condition cartels*, which fix terms and trade conditions.
3. *Quota cartels*, which limit and regulate the output of an industry to prevent overproduction and ruinous price competition, usually by the apportionment of orders upon an agreed basis. This type very often distributes its products through a central sales agency and is similar to the old American "blind pool."
4. *Territory cartels*, which apportion exclusive territories.
5. *Patent cartels*, which pool and share patent rights. This type constitutes an important part of the international cartels.
6. *Standardization cartels*, which simplify and standardize their products.
7. *Purchasing cartels*, which establish central purchase agencies.

Class 3. Common Interest. The community of interest type of combination, strictly speaking, seldom possesses a corporate entity except when an incorporated community acts in its own interest against another community. The term is used here rather to include all classes of combinations not covered by classes 1 and 2, which although often loosely organized, nevertheless possess considerable power. Before they were declared illegal in this country, interlocking directorates would have come within this class. This method of combination is very prevalent abroad. Further discussion of

the common interest type of combination will be found in a subsequent section.

Legal Situation. A somewhat clearer understanding of the various classes of combinations may be secured by an examination of the legal history of combinations in various countries. This is briefly summarized in the paragraphs which follow:

United States. Abuses arising from combinations in the United States resulted in the enactment of regulatory legislation beginning in 1890. The Sherman Law, enacted in that year, made illegal "every contract, combination in the form of trusts or otherwise, or conspiracy, in restraint of trade or commerce among the several states, or with foreign nations" and forbade anyone "to establish or attempt to establish a monopoly."

This Federal Anti-Trust Law was supplemented by the Clayton Act and the Federal Trade Commission Law in 1914. The first made it illegal to acquire shares in another company when such action leads to "a real diminution of the competition between companies" or "tends to establish a monopoly," and provides against interlocking directors and officers, discrimination in favor of selected customers or against competitors.

The Federal Trade Commission was created to examine and report on commercial procedures which constitute an infringement of the anti-trust laws and to prevent unfair competition. Its activities are confined to interstate and foreign business, and do not include supervision of banks, railways, labor unions and certain agricultural interests. An important function of the Commission is that of advising with those who contemplate effecting a combination in regard to the probability of its legality. In 1918 the Webb-Pomerene Law excluded from the provisions of previous anti-trust legislation combinations engaged exclusively in foreign trade.

American Cartels. Anti-trust legislation in this country resulted in the disappearance of certain sorts of cartels. The trust agreement as a method of monopolistic control, the price cartels, the quota cartels, and the territory cartels whether in the form of blind pools or of "gentlemen's agreements" disappeared, violently or quietly, depending upon circumstances.

The trade condition cartel and the standardization cartel have survived in the form of trade associations of which there are at present in excess of 12,000 in the United States.

Patent cartels exist, certain companies being licensed to manufacture under patents held by others. Selling companies exist which dispose of the product of a number of companies manufacturing different products. Purchasing cartels exist in the form of retailers and wholesalers banded together to carry on mass purchasing.

Undoubtedly other types of combinations could be affected by means of long-term contracts, without the trouble and risk of corporate combination, if it were profitable to promote them.

Germany. The tendency in Germany in the past has been to effect combinations by means of cartels while the United States has favored holding companies, consolidations, and mergers. There have been several reasons for this. The German corporation law of 1870 was so lenient and so much abused that strict regulations for corporations were introduced in 1884,

Cartels, however, were tacitly recognized and a strong central government dealt with abuses. In 1923, the Cartel Decree was passed which was directed against the abuse of economic power. Cartels served very well so long as wastes of competition and sales were being principally dealt with. However, as wastes of production also began to be dealt with under more recent programs of rationalization,¹ a highly centralized and powerful administrative and executive organization became necessary. This has more recently led to an increase in combinations by means of holding companies and the like.

Both countries seem to have adopted the principle of prosecution when acts contrary to the public good are committed, basing action upon an examination of results, in each case, rather than attempting to define in exact detail just what is lawful and unlawful.

Other Countries. In Great Britain combinations are not governed by any special statute but are subject to the common law doctrine that restraints on trade are bad. No legal authority to require information in regard to the operation of combinations now exists. A somewhat similar situation exists in France and Italy, although in the former country a law was passed in 1926, making unreasonable price manipulation illegal.

General. Combination is instinctive. Since the dawn of history not only has man, but a great part of the animal kingdom, combined in order to survive and to attain their objectives in the struggle for existence. It is extremely difficult to exterminate an instinct by means of legislation. In a democracy effective legislation and satisfactory enforcement depend upon, and vary with, the ethical standards of the majority of the community.

So long as the human race exists, there will be combinations. So long as business is conducted primarily for profit, combinations to increase profits will be formed. At present there are three principal corporate forms of combination. These are permitted by law so long as they avoid acts believed contrary to the public good. At times legislation and enforcement interfere with the attainment of this objective. At other times business methods are adopted leading to abuses which arouse public opinion and force drastic legislation. In this respect anti-trust legislation seems to follow the course of legislation in general, with the maintenance of justice depending upon the reasonable conduct, self-restraint and regard for public good displayed by all parties concerned.

Economic Developments Affecting Combinations. From the standpoint of successful operation the economic form assumed by a combination is much more important than its corporate form. An understanding of the various economic types of combinations is necessarily predicated upon an understanding of certain economic developments affecting combinations.

These developments may be briefly summarized under:

1. Increased ease and speed of communication.
2. Increased ease and speed of transportation.

¹ Rationalization was defined in the final report of the World Economic Conference as "the methods of technique and organization designed to secure the minimum waste of either effort or material. It includes the scientific organization of labor, standardisation of both materials and products, simplification of processes and improvements in the system of transport and marketing."

3. Miscellaneous changes in the industrial and economic structure.
4. General education in economics and management.

The following paragraphs set forth briefly and incompletely, in statistical form, the principal changes which have taken place in these fields in the United States:

1. *Communication.* From 1860 to 1910 the revenue of the United States Postal Service increased from \$.27 to \$2.43 per capita or 800 per cent. From 1910 to 1920 it increased 69 per cent and from 1920 to 1927 it increased 40 per cent reaching the sum of \$5.76 per capita during the last year. Rural free delivery routes instituted in 1897 increased from 28,000 miles in 1900 to 993,000 miles in 1910, to 1,152,000 miles in 1920, and to 1,271,000 miles in 1927.

From 1902 to 1912 the number of telegrams and cables sent by United States companies increased 20 per cent; from 1912 to 1922, 75 per cent. Bell Telephone System messages increased 47 per cent from 1910 to 1920 and 65 per cent from 1920 to 1927. Telephones connected increased 45 per cent from 1920 to 1927. Wireless messages increased 85 per cent from 1907 to 1912 and 730 per cent from 1912 to 1922.

Mileage traveled by air mail increased 9,440 per cent from 1918 to 1924 and 53 per cent from 1924 to 1927. From New York a letter can now be sent to San Francisco in little more time than it formerly required to send one to Chicago.

The value of radio sets and accessories sold from 1922 to 1928 increased 980 per cent. The present radio audience is estimated at 40,000,000 as against 75,000 persons in 1922. No figures covering television are available.

It is estimated that there are 20,000 moving picture theatres in the United States whose receipts aggregate over \$750,000,000 annually. No figures are available covering the talking moving picture industry.

It is estimated that about \$1,250,000,000 is spent annually on advertising, nearly \$500,000,000 being spent for national advertising—about half in newspapers, a third in magazines, and the balance in outdoor and street-car advertising.

These figures indicate the immense increase in the ease and speed of communication, especially during the past few years.

2. *Transportation.* From 1860 to 1910 the railroad mileage operated in the United States increased from 30,000 to 240,000 or 700 per cent. From 1910 to 1920 it increased 8 per cent and from 1920 to 1926 it decreased .43 per cent. From 1906 to 1910 ton miles of freight carried increased 18 per cent as against an increase of 62 per cent from 1910 to 1920 and of 8 per cent from 1920 to 1926. Passengers carried one mile increased 29 per cent from 1906 to 1910, 46 per cent from 1910 to 1920 and decreased 25 per cent from 1920 to 1926. From 1923 to 1926 water-borne commerce of the United States of all sorts increased 13 per cent.

From 1910 to 1920 passenger car registration increased 1,695 per cent and from 1920 to 1928, 162 per cent. Track registration increased 9,960 per cent from 1910 to 1920 and 211 per cent from 1920 to 1928. It is estimated that busses increased 62 per cent from 1925 to 1928.

From 1904 to 1914 the total mileage of highways in the United States increased 14 per cent; from 1914 to 1921, 20 per cent; and from 1921 to 1926, 4 per cent. Surfaced road mileage increased 67 per cent from 1904 to 1914, 51 per cent from 1914 to 1921, and 45 per cent from 1921 to 1926. It is estimated that 7,000 miles of concrete roads are now being built annually.

Airplane production increased 160 per cent from 1921 to 1925, 153 per cent from 1925 to 1927, and 105 per cent from 1927 to 1928, with an estimate of a further 193 per cent increase for 1929. The Department of Commerce estimates all classes of airplanes flew 70,000,000 miles in 1928.

These figures indicate the enormous increase in the ease and speed of transportation, especially during recent years.

3. *Miscellaneous Changes in the Industrial and Economic Structure.* From 1860 to 1890 the wealth per capita in the United States increased 102 per cent; from 1890 to 1900, 12 per cent; from 1900 to 1912, 67 per cent; and from 1912 to 1922, 50 per cent.

From 1919 to 1924 the value of mail-order sales increased 5 per cent, grocery chain sales 116 per cent, 5 and 10 cent chain sales 87 per cent, wearing apparel chain sales 172 per cent, drug chain sales 53 per cent, cigar chain sales 39 per cent, shoe chain sales 33 per cent, and candy chain sales 91 per cent, as compared with increases of 23 per cent, 80 per cent, 39 per cent, 93 per cent, 46 per cent, 10 per cent, 14 per cent and 18 per cent for the respective classes from 1924 to 1927. During the first period the value of sales of nine wholesale lines decreased 11 per cent, and during the second period the value of sales decreased 3 per cent. Department store sales increased 27 per cent during the first period and 7 per cent during the second.

Production of electric power by public utility power plants increased 68 per cent from 1922 to 1927, kilowatt hours *per capita* consumed increased 55 per cent, and the number of electric service customers increased 71 per cent. From 1922 to 1928 the percentage of the total population living in electric lighted dwellings increased from 39 per cent to 67 per cent. The percentage of electrification of manufacturing establishments increased from 60 per cent in 1923 to 75 per cent in 1927.

The number of students annually enrolled in collegiate institutions increased 60 per cent from 1890 to 1900, 48 per cent from 1900 to 1910, 121 per cent from 1910 to 1920 and 75 per cent from 1920 to 1926.

These figures indicate the rapid increase in wealth, the trend toward mass distribution, and the immense increase in popular electrification and education in recent years.

4. *Education in Economics and Management.* During the war the people discovered that the educated officered the army. This stimulated interest in education. The general business slump in 1920 resulted in an immense increase in economic consciousness on the part of the public at large. All classes wanted to know just what had happened to them, and why, so that if possible it might be prevented from ever happening again. During the ten years following the war publications dealing with business, industry, finance and economics showed a large increase. Financial services multiplied.

The war stimulated interest in the science of management. Driven by the necessities of increased demand and lack of manpower nations scrapped

tradition and sought the one best way to produce. Knowledge was pooled. Resources were pooled. Governments effected industrial combinations of a sort which exceeded the wildest dreams of the imagination. The world learned to cooperate and the public became combination conscious.

Education in economics, in management, and in the value of combination naturally stimulated combinations. This education also stimulated speculation. Speculation has in turn stimulated further education.

Summary. The result of such unprecedented increases in ease and speed of communication and transportation, in education, in economics, in management, in finance, and in the value of combinations, coupled with such vital changes in the industrial and economic structure as have been cited, could only result in very great stimulation of the combination movement. On a basis of time consumed in communication and transportation continents are now closer together than contiguous counties were in former times. The war demonstrated the value of combination and education. Science has revolutionized the life of the people.

More specifically combinations were stimulated by:

1. The overbuilt condition of industry after the war.
2. The development during the war of mass production which resulted in the general introduction of:
 - a. Scientific methods of administrative and executive management applied to finance, sales, and production.
 - b. Simplification.
 - c. Standardization.
 - d. Labor-saving machinery.
 - e. Progressive machining and assembly.
3. Increased cost of equipment required for mass production.
4. Improvements in technical practice.
5. New inventions as the result of research.
6. The high cost of distribution caused by attempts to dispose of the increased output resulting from the above, and from attempts to further increase output and so reduce costs by high pressure sales methods, national advertising, national distribution, direct contact with retailers, etc.
7. The application of mass methods to purchasing and retail distribution through the medium of the chain store. This movement was further assisted by the trend of population toward cities, by the development and popularization of the automobile, and by the growth of hard-surfaced highways.

In the section which follows an attempt will be made to indicate the results of these vast and recent developments as they affect the economic form of combinations.

Economic Types of Combinations. The principal economic types of combinations, classified on a basis of their economic reason for existence, are defined in the following paragraphs:

1. *Horizontal.* The horizontal combination, which is the commonest type, in its simplest form, is a combination of industries manufacturing a single product—as matches or automobiles.
2. *Vertical.* The vertical combination is a combination of a number of industries of such a sort and in such a manner that the finished product of one becomes the raw material of the next. The complete vertical combination

begins with the raw material as supplied by nature and ends by placing the finished product in the hands of the ultimate consumer.

3. *Allied Industry.* The allied industry combination is a combination of industries manufacturing articles of a similar nature, or articles which can be sold to the same market.

4. *Chain.* The chain type of combination is a combination of businesses serving the public in some capacity, usually in different localities, which can secure certain advantages by combination.

5. *Local.* The local type of combination is a combination of industries located in a simple community, and formed usually for the purpose of strengthening their strategic position.

6. *Seasonal.* The seasonal type of combination is a combination of industries whose peak loads of business occur during different seasons of the year for the purpose of distributing the load throughout the year in the interest of more efficient operation.

7. *Cartel.* This type of combination includes any form of combination formed for mutual benefit on a contractual basis.

8. *Common Interest.* This type of combination, which is the least organized, *per se*, of any of the types enumerated, may assume almost any form for the purpose of improving conditions in which the parties involved are interested.

9. *Mixed.* This type consists of combinations embodying features of more than one of the types previously enumerated. Furthermore it should be observed that one or more of the various types mentioned may take place on the manufacturing level, on the wholesale level, or on the retail level of production and distribution, or on a number of such levels. This makes it difficult to empirically classify existing combinations and to demonstrate statistically the exact prevalence of each type.

1. *The horizontal combination* was one of the early American developments because of the fact that the original idea of combination was to effect a monopoly. Destructive competition, like war, eventually induces a desire for peace, and, as competition became unbearable in certain industries in the late eighties and the early nineties, the thought naturally occurred that if all the manufacturers of a given product could combine and raise prices, business would be very profitable indeed. The early combinations, therefore, consisted of manufacturers who combined with this end principally in view. From 1897 to 1900 extensive use was made of the corporate form known as the "voting trust" under which manufacturers turned their stock over to trustees and received trust certificates in exchange. As a result of this movement, the anti-trust legislation previously referred to was instituted in 1890, trusts were proved illegal, and the Supreme Court ordered the dissolution of a number of concerns of this type which were particularly active between 1904 and 1914. In 1912 the decision in the case of the United States Steel Corporation virtually legalized combinations which did not control more than 40 per cent of the output of an industry.

In spite of legal restrictions the horizontal type of combination has continued to flourish. Such combinations have been profitable to promoters and investment bankers; they have provided founders of businesses who

wished to become less active with leisure and with diversification for their investments; they have enabled young men of ambition to increase their power and prestige; they have enabled the public to participate in the earnings of closely held companies.

In addition, even though price control has been proven illegal, such combinations have retained very real economic reasons for existence. For example this type of combination:

- a. Tends to insure a lower cost of production through continuous quantity production of standardized articles.
- b. Saves expense through the consolidation of administrative, executive, sales, advertising, and similar departments and activities.
- c. Saves transportation charges on raw material and finished products.
- d. Provides for pooling of knowledge, methods and processes.
- e. Makes mass purchase possible, with assurance of uniform quality and low cost of raw materials.
- f. Makes maintenance of superior quality possible.
- g. Reduces interest and depreciation on stores of raw material and semi-finished and finished products.
- h. Reduces amount of capital required per unit produced.
- i. Increases ease of financing, since securities are more liquid and more stable.
- j. Permits the most effective use of research laboratories.
- k. Increases security of patents and trade marks.
- l. Permits use of highest class of administrators and executives.
- m. Permits retention of highest class of staff experts, lawyers, engineers, chemists, accountants, statisticians, etc.
- n. Makes comparative management possible together with the most effective administrative methods.

Furthermore when a horizontal combination is formed of concerns manufacturing heavy goods, which are confined to the locality in which the plant is located by high freight rates, it is possible to apply pressure, in cases of destructive competition, to isolated competitors by cutting prices in that locality while still maintaining them at profitable levels in other districts.

An enumeration of the industries which have taken advantage of this type of combination would read like the roster of the United States Chamber of Commerce. While every such combination has not been successful, it must be remembered that management, fashion and price are even greater factors in the success of a business than combination, and that acquisitive ability does not necessarily imply administrative and executive ability. The fact remains that horizontal combinations have been popular and are likely to remain popular for some time to come.

2. The vertical combination probably originated in this country in corporate form with the Carnegie Steel Company, although the type received the greatest publicity in Germany after the war when, under the title of *Konzern*, it very largely replaced the cartel. Owing to financial and raw material conditions, it ran wild until about 1925 when, with the collapse of the *Stinnes Konzern*, it was largely replaced by the cartel; although vertical combinations that were strictly complementary and in line with the tendencies toward the reduction of all costs including those of production, distribution and

competition (rationalization) survived. At present the Ford Motor Company probably represents one of the most complete examples of the vertical combination in this country. The Anaconda Copper Company is another example and a number of oil companies are almost completely integrated. Certain other companies such as the American Telephone and Telegraph Company with its subsidiaries, Sears, Roebuck and Company with its manufacturing plants, and certain textile and food companies are examples of partial verticalization. Recent combinations of moving picture producing companies and theatres chains are also examples of this type.

The economic reasons for existence of the vertical type of combination are much the same as for the horizontal type although savings in transportation are not likely to be as great. The assurance of uniform quality and the absence of fluctuation in the cost of raw materials is likely to be somewhat greater. Somewhat less cash is required because payment for raw and semi-processed materials between successive integrated units can be made in the form of credits. Comparative management is not so strong a factor in the case of the vertical type combination as in the case of the horizontal type.

Furthermore, in cases of destructive competition it is possible with this type of combination to apply pressure to competitors by foregoing profits on one or two levels while retaining them on others; and thus securing profits from the structure as a whole, while reducing final prices below competitors' cost of production.

The success of a vertical combination depends largely upon the care with which integration is effected. For instance:

a. It is necessary that the structure be balanced. Each unit should be capable of absorbing the full output of the unit below it. Otherwise the unit below will be forced to operate at part capacity or to sell part of its product to competitors at considerable disadvantage. Consider the position of an automobile parts factory shipping half its product to the finished car unit above it in a vertical combination and forced to sell half its output to competing car manufacturers.

b. Every unit must be an efficient, low cost producer. Otherwise there will be times when the unit above will be handicapped by being forced to take materials at prices above which they could be bought in the open market. This has seriously interfered with the success of certain British steel companies who have had to take the coal of subsidiaries at a cost in excess of open market prices.

c. It is usually inadvisable to carry the verticalization downward below the point of reasonable control. For instance in the case of raw materials produced from mines the quantity produced can be controlled and the probable cost predicted. Vertical combinations using wheat, cotton, livestock, etc., whose quantity and price are dependent upon the weather and upon the idiosyncracies of a large and highly individualistic group of workmen so far have found it much more profitable to buy in the open market, rather than to undertake the production of the basic raw materials.

3. The allied industry type of combination is by no means new in this country. International Business Machines Corporation, formerly the Computing-Tabulating-Recording Company, represents one of the oldest and

most successful examples of this type. A number of similar combinations have since been effected in the same general field.

A more recent allied industry combination was formed in the hotel supply field and included companies manufacturing refrigerators, carpets, beds, furniture, wood products, pianos, and two sales corporations. There are also such combinations in the builders supply, furniture and floor covering fields. The recent combination of a radiator company and a manufacturer of sanitary ware and plumbers' supplies was of this type.

Public utility combinations are frequently of this type selling heat, light, power and transportation, gas and electric power, etc. In many cases a certain amount of verticalization exists, such companies owning coal mines, etc.

Certain trade-marked food companies have acquired a considerable number of other companies manufacturing nationally advertised food products. There have been similar combinations in the grocery and drug fields.

The economic reasons for existence of the allied industry type of combination are much the same as for the horizontal type although savings in transportation and from the combination of sales forces is not likely to be so great. In the early days of allied industry combination, attempts were made to induce salesmen experienced in only one line to sell the complete line. In a great many cases this was found to be impracticable, with the result that in most cases less attempt is now made to combine the sales forces at the time of combination.

This type of combination frequently results in the attainment of a higher degree of manufacturing efficiency because it permits allocation of a single product or group of products to single plants which can then specialize on this product or group with extremely beneficial results.

The allied industry type of combination is particularly effective in dealing with destructive competition, since it can apply pressure by cutting prices in one field while still operating at a profit in others.

Furthermore, in certain cases one product possesses such merit or is so protected by patents that purchasers who need this product can be induced to purchase the other products of the combination. This is a particularly effective method of combating demand for price reduction from mass buyers such as chain stores, etc.

4. The chain type of combination is as old as the branch office combination which permits the extension over wide territory of principles and methods which have proved successful in one locality. The chain store is of course the most recent and spectacular development. Besides these there are chains of bakeries, banks, hotels, barber shops, gasoline stations, theatres, taxicab concerns, etc.

The chain store movement has grown so rapidly during recent years that no authentic figures are available covering the situation, although sales through this medium in the United States have been estimated as in excess of \$8,000,000,000 annually, constituting more than 20 per cent of all retail sales. The situation may be summarized as follows:

- a. A situation favorable to the growth of the chain store movement was created by:

- (1) The increase in manufacturing capacity due to the overbuilding of plants during the war and to increased efficiency secured since the war by means of standardization, mass production, labor-saving machinery and more exact methods of management.
 - (2) The increase in the cost of distribution due to high pressure sales methods, large advertising appropriations, and the coverage of greater territories for the purpose of disposing of greater volume.
 - (3) The disappearance of retail outlets in small towns due to the popularization of the automobile and the construction of hard-surfaced roads.
 - (4) The general weakness and inefficiency of the small retailer generally.
- b. The development by men of unusual ability of standardized methods of retailing, based on the scientific determination of such controlling factors as store location, layout, high turn-over goods, buying habits of the public, etc., contributed to the growth of the chain store to the point where mass buying direct from the manufacturer became possible; with attendant vertical integration extending in some cases from the purchase of raw material to the disposal of goods to the ultimate consumer, as in the case of the manufacturers' and mail order chains.
- c. As a result of the economies of distribution effected by this integration and growth of the chain store movement, the manufacturer-wholesaler-retailer system of distribution has been almost destroyed in some fields and is being seriously threatened in others.
- d. Although retailers and wholesalers are forming cooperative associations to resist the chain store movement by adopting its methods, such expedients seem to be successful only where sufficient ability and concerted action exist to permit an approach to chain store efficiency.
- e. Meantime the chain store movement is growing rapidly, and the future of the manufacturer-wholesaler-retailer system of distributing the great mass of merchandise consumed is in many instances so seriously threatened that the future of the great majority of its members would seem to depend upon their ability to become part of or associated with integrated groups, capable of manufacturing *en masse* and distributing merchantable goods at a cost sufficiently low to compete with existing integrated chains.
- f. Such integration seems to be taking the form of:
- (1) Associations of retailers with the wholesaler acting as purchasing agent.
 - (2) Retailing by wholesalers and manufacturers through their own outlets.
 - (3) Entrance of mail-order houses into the chain store field.
 - (4) Exchanges of stock between manufacturers and chain stores.
 - (5) Consolidations of manufacturers of different articles whose goods can be sold through chain stores or department stores, with each other, and with existing chains.
 - (6) Leased departments in community stores, and long-term contracts similar to the European cartel.

The economic reasons for existence of other types of chains are similar in principle to those enumerated under paragraph *b* above. In the case of bakery chains, theatres, and gasoline stations considerable vertical integration is also taking place. In the oil industry this is coupled with horizontal combination. The whole chain movement is so vast and is extending so rapidly that the eventual outcome is difficult to foresee with any degree of certainty.

5. The local type of combination is rather rare owing to the lack of any well defined economic reason for existence in most cases. A combination of this type was recently formed in the West which comprised a sewing machine company, a piano company, and certain furniture plants located in one town. One was once formed in an Alaskan city which combined nearly every business house in the locality. During the war, industries united in various cities to secure, train, and deal with labor.

6. The seasonal combination is quite common and is the result of attempts to utilize labor and equipment throughout the year, rather than at stated seasons only. Examples of this type are combinations of coal and ice companies, coal and brick companies, coal and builders' supply companies, oyster and ice cream companies, and the like.

7. The cartel type of combination, which is based upon a contractual relation undertaken for mutual benefit by interests possessing similar aims, ranges from the trade associations whose members agree to pay annual dues to associations which (in Germany) fix prices and establish production quotas with penalties for violation. The various types have been quite fully discussed in the section on corporate types.

In this country the trade association has been encouraged by the government and has done much to stabilize industry. Uniform methods of accounting and uniform trade discounts have been established. Standardization, simplification, and the elimination of waste have been encouraged. Group advertising has been undertaken. Research has been financed and encouraged. Information in regard to production, sales, and technical methods has been disseminated and considerable benefit has been secured without arousing criticism from government authorities.

8. The common interest type of combination was at one time well organized in this country by means of what was known as "interlocking directorates." These were discouraged under the Clayton Act in 1914. At the same time there is no reason why men who can bring business to a company should not be elected to its board of directors. There is no law to prevent an individual, a banking group, or an investment trust from owning stock in competing companies. There is nothing to prevent such interests conferring in regard to matters of mutual concern and advising with executives, provided no statute is violated.

Investment trusts have increased and grown so rapidly in the last year or two that certain large corporations have created special departments to deal with them. They have also been used as a means of effecting consolidations. In certain instances they approach closely the holding company.

Certain manufacturing concerns have sold chain stores substantial blocks of common stock on advantageous terms in order to secure their interest in marketing the lines manufactured.

It is very common for the citizens of towns, states and nations to unite to stimulate the use of goods manufactured within their own boundaries. Certain classes such as farmers, laborers, and the like form associations and unions to further their own interests.

While many such communities of interest are not sufficiently organized to permit strict definition as combinations, nevertheless they are in effect

combinations and collectively they exert immense power. Under the circumstances they must be given consideration in any analysis of the combination movement.

Export Combinations. In 1918 the Webb-Pomerene Act provided for the exemption from anti-trust laws of any combination engaged solely in export trade, provided it in no way interfered with domestic trade, the export trade of a domestic competitor, or with domestic prices. This act was designed to aid American exporters to meet on equal terms the aggressive competition of the more powerful combinations in foreign countries.

In all countries the mobilization of production and distribution, in response to the exigencies of war, revealed to the nations of the world the advantages of coordination and combination in industry. As a result, export trade associations and combinations in foreign countries increased greatly both in numbers and in strength, aided and encouraged and sometimes participated in by their respective governments which recognized the importance of export trade cooperation.

Although the largest manufacturers possessed effective export departments some of which even conduct scientific market analyses and promote and finance enterprises which will consume their product, smaller manufacturers were at a considerable disadvantage. The new law in the United States encouraged the formation of combinations which might compete abroad, offer a diversified line of products, and secure numerous economies of distribution and standardization.

In accordance with the provisions of this law, a number of combinations have been formed. These include export associations and corporations covering copper, steel, oil, zinc, lumber, sugar, flour and wheat, milk, sulphur, tires, abrasives, cement, locomotives, food products, paints and varnishes, fertilizers, buttons, etc.

European Types of Combinations. *Great Britain.* Holding companies, consolidations, and mergers are found in Great Britain although few are purely of the types previously described. Many are holding companies to some extent and consolidations to some extent, while they may also have allied themselves with other companies by means of exchange of shares or interlocking directorates. There are a number of instances of the above mentioned types dominating and existing side by side in the same industry with cartels which are known in Great Britain as "terminable associations." On the whole, however, Great Britain has in the past proved by no means so fertile a field for the growth of organized combinations as the United States and Germany.

The cartel (terminable association or gentlemen's agreement) has been common at all times, especially in local trade. These associations which aim at limiting competition attain their end principally by fixing minimum prices and by variations of the pooling and rebate systems.

Vertical consolidations exist in the steel industry together with various types of cartels. The same is true in engineering and shipbuilding. One of the most complete verticalizations in the world exists in the British soap industry, the concern in question producing 75 per cent of all soap made in the country. Pig-iron manufacturers control the bulk of their supplies of ore and coal.

Certain consolidations partake both of a vertical and horizontal character as in the case of the chemical and allied industries in 1926. Consolidations of considerable size exist in the textile, explosive, tobacco, and distilling industries. Consolidations have recently been effected in the coal, cotton, and fertilizer fields and there have been mergers in the electrical industry.

Recent developments seem to indicate that the cartel has broken down to a considerable extent, as is usual under intense competition. As a result, the highly individualistic attitude of the British industrialist of the past has begun to succumb to the necessity for combination in the interest of effective large scale production which is being undertaken under a program of rationalization.

France. Although France contains some large and well-managed vertical combinations, especially in the motor, engineering, shipbuilding, and steel industries, large combinations are rarer than in Great Britain. This is partly due to fear of prosecution for unreasonable price fixing, partly to a tendency toward individualism and secrecy, and partly because luxury goods which constitute a considerable proportion of French production do not readily lend themselves to mass manufacture.

Four combinations dominate the electrical industry. The aluminum industry is practically dominated by one concern. Two concerns dominate the heavy chemical industry. Combinations have recently occurred in the dyeing, light chemical, cement, and wine industries.

Cartels exist principally in the form of the *comptoir* which is an incorporated trading company composed of manufacturers who turn over to it the sale of their products.

Consolidations and mergers seem to be following the general tendency and increasing. Chain combinations are increasing rapidly, principally in the grocery and department store fields. Sales in the former were estimated at \$220,000,000 in 1927.

Germany. The situation in Germany has already been covered in sufficient detail. The cartel was replaced after the war by the vertical consolidation which has since been replaced in many cases by the cartel.

The present trend is toward consolidation in order to increase the effectiveness of production under a program of rationalization. This is being carried out under highly centralized and powerful central administrative and executive control in the coal, iron, steel, air transport, metal, engineering, copper and brass, printing, chemical, dye, potash, cement, and other industries.

Italy. Italy is handicapped industrially to a considerable extent by lack of raw materials. However, there are some large vertical and horizontal combinations especially in the engineering, shipbuilding, steel, and motor industries as well as in the public utility field.

International Combinations. It has been estimated that there were over a hundred international combinations, principally of the cartel type, before the war. These covered transportation, coal, oil, tobacco, cotton, ore, metal, stone, earth, electrical products, chemical, textiles, porcelain, paper, etc. As a rule the object of these combinations was the regulation of competition and the exclusion of foreign competition from the home markets of the participants (dumping).

Sales territories were apportioned, prices were regulated and credit terms, packing practice and selling methods arranged. Sometimes patents and technical knowledge were exchanged.

While most of these combinations were broken up during the war, many have since been reorganized. Present developments indicate that the international combination is likely to be more far-reaching in the future than it has in the past. The movement has already been carried on to an extent greater than at any time in history. It marks a reaction from the extreme economic nationalization indicated by discriminatory tariffs, commercial treaties, and other governmental controls and points a return to international solidarity. Leading authorities consider the movement to be only beginning.

General Conclusions. Any analysis of the situation inevitably leads to the conclusion that the combination movement is growing and extending rapidly throughout the industrial, commercial, and financial world. Increased speed of communication and transportation was responsible for the movement during the last quarter of the nineteenth century. The movement was vastly accelerated by the World War which broke down the barriers of tradition, individualism, and secrecy; and substituted cooperation, coordination, and combination; stimulated education in management, economics, and finance; and further speeded up communication and transportation.

The combination and rationalization of industry, nationally and internationally, coupled with the ownership of industry by the people at large through the wider public distribution of industrial securities, are leading rapidly toward changes in our civilization of the utmost importance.

What the final result will be or what difficulties will be encountered, before the economic and industrial democracy which many foresee will be firmly established, are at present beyond the scope of our vision. We do know that the transition is becoming daily more rapid and that the results will be far-reaching. Beyond that point prediction is as yet unsafe.

FACTORS TO CONSIDER IN WORKING OUT MERGERS

BY A. D. BERNING, *Partner, Ernst & Ernst*

The many mergers that have been made and the many that are in the making afford ample laboratory material for doing the research work necessary for the determination and study of at least the principal factors to be considered in working out mergers.

But to qualify as an authority on these factors, one would need a great many opportunities to follow very closely the process of merging from conception through to conclusion and then of watching each of the resulting unions for a period of its operation as a going business.

I have not lived long enough nor have I had opportunity in a sufficient number of cases, to qualify as an authority on the subject. I have participated however, in a number of meetings where the economic, legal, financial and other phases of the merger were carefully reviewed and discussed and after consummation of the merger, have had opportunities to discuss with the management the problems that confronted them in the practical working of

the merged operations. The proof of the pudding is in the eating; but in the case of mergers digestion must be taken into account. The digestive process, in some cases, is prolonged and at times painful. If we watch it carefully, we can learn much. This knowledge we can transmute into what we may call factors to consider in working out mergers.

The Human Factor. Some of the factors that must claim our attention are, of course, working capital, valuations, plant capacities, geographical location, patents, trade-marks, earning power, merchandising, distribution, and so on. All of these are important and no venture is likely to succeed unless they are duly considered. Too frequently, however, we are tempted to dwell on these physical and technical aspects of the proposition and call it a day without paying much attention to the human factor.

The human factor, if we can call it that for want of a better name, is frequently more potent in influencing the issue, to merge or not to merge, than those material quantities that can be measured more or less satisfactorily, with some kind of yardstick. Whatever may be the factors, the interested parties will be influenced in their consideration of them by what their best interests appear to be. More projects that had for their object the merging of business interests have fallen by the wayside and been left abandoned there because of the human factors that entered into the negotiations, than any that have failed as a result of disagreement on relative values. Yardsticks that have so far proven fairly satisfactory in the measurement and valuation of physical factors are not adapted to gauging the human factor in its many phases and complexities.

Compatibility. Willingness on the part of some to throw in their lot with others is quite a factor and worthy of a great deal of consideration. Mutual respect based, of course, on mutual confidence that has for its foundation the character and the habits of the interests to be merged, has had its effect in finally consummating deals of this kind. I know of a case where the people in control of a fine old company refused a very substantial offer to sell out to other interests, their sole reason being that they held their business and its goodwill in too high esteem. Some time later, they accepted a much more modest amount for their interests from another competitor who they felt would provide more harmonious surroundings.

So we come to a consideration of the character of the interests involved as an important factor in working out mergers.

"Trading" and Compromises. In merging, the trading abilities of the participants are directed to the protection and if possible, the enhancement of their values. Merging involves trading in all that the term implies. There is that which is written in the contract and that which may be implied or understood; and that which is without the contract is sometimes the compromise.

Not infrequently, the compromises, or if we may use another term, the "implied obligations" which a management may feel it owes for goodwill, influence or in recognition of stock ownership or some other real or imaginary consideration, contribute the most to the prolonged and painful digestive process which may follow the merging operation.

Every Merger Is Different. No two mergers are similar or even comparable in many of their major problems. Every merger, large or small, has its own

peculiarities. One merger involves factors that another does not and factors that may be common to both will have a different order of importance in one than in the other. There may be, for example, serious problems related to ownership of units to be included in a merger. Many times when the securities of one or more units are lodged in trust estates or in the hands of various individuals, the nature of the securities to be issued has to meet individual requirements. In many cases a much larger amount of banking assistance is needed because of the cash payments to be made to owners. As a consequence the banker is often in a much stronger position to dictate the particular kind of securities he desires to purchase to meet existing market conditions.

In a recent case it was possible for five companies to merge without new financing. This was, in many respects, an ideal situation. The capital structure could be created with a view to minimum fixed charges because all stockholders of the five companies were willing to accept all common shares.

However, there are certain basic questions that apply to all business consolidations and it is to these that I shall direct your particular attention.

Six Fundamental Factors. The present era is primarily characterized by mergers. In practically every form of industrial activity, individual enterprises are rushing into the trend. What then prompts these separate business concerns to weld their physical and intangible assets, goodwill, and future prospects? If we have been students of the movement, we are conscious of many mergers which are now having varying degrees of success. In a number of cases we deduce that the participants, when their merger was conceived, did not realize or give sufficient attention to the importance of the fundamentals and have suffered consequent disappointments.

From experience, I should say that the more important factors to consider in any merger movement are:

1. Economic and legal soundness of the merger.
2. Management.
3. Financial position.
4. Earning power.
5. Formula or plan of merger.
6. Launching the merged business.

Economic and Legal Soundness. The question of economic and legal soundness is one which should be very carefully studied in advance of all others. Unless there is a sound economic reason for a business consolidation from the more important viewpoints, it can hardly be justified. By sound economic reason I mean sound expectancy that the combined concerns will be able to operate with greater benefit to the old owners and the public as well. There should be the least possible doubt about the original investment of the contributors being kept intact.

Without discussing the legal aspects I should mention that the provisions of the Sherman Anti-Trust law or the Clayton act, which respectively have to do with combinations in restraint of trade and creation of a monopoly, may require consideration. Also the problem of taxes, because the cost of doing business in the different states varies greatly and the trend of state taxation is becoming increasingly important. In these and many other matters the advice of recognized legal counsel is a prime necessity.

Points of Economic Soundness. The factor of economic soundness has many important angles from which a proposed amalgamation should be visualized. The physical facilities employed in the business should be modern and well-adapted to its purpose and at least on a par with the facilities of other companies in the same business. The properties of manufacturing companies should be viewed from the standpoint of not only their reproductive and present sound values but also their useful value to the new company. The probable future of the industry should receive careful thought as well as the probable ability of the new company to meet any new conditions which may arise and affect its stability.

The location of plants is important. For example, a contemplated merger of manufacturing companies situated on the eastern seaboard would call for consideration of the need of facilities at strategic points in other sections of the country for both production and distribution. There have been many mergers wherein the locations of the plants were such as to presuppose subsequent large expenditures in new plant construction. This has had the two-fold effect of unnecessarily tying up capital in new permanent assets while making certain properties in the original capitalization more or less obsolete, thereby reducing the value of the securities issued at the time of organization. I could cite cases of merger, actually consummated in which this problem, having been overlooked or not squarely met at the proper time, resulted in unanticipated revamping of the whole factory program or the establishment of extensive branch and warehouse organizations to improve distributing facilities. This is not only a matter of capital—capital tied up permanently—but also one that involves many items of overhead expense.

In view of labor conditions, labor costs, freight rates, exigencies of distribution, and so on, a merger may necessitate radical rearrangements of manufacturing, whereby production of a particular class of products can be concentrated in one plant and production of a variety of products consolidated in another. When this is the case, the inevitability of manufacturing problems and of outlays for more or less extensive plant changes should be taken into account while the amalgamation is still in its prospective stage.

Concerns that contemplate merging on the basis of producing somewhat similar lines of merchandise must give sufficient thought to the very practical question of differences in quality and prices. Such differences may have made the lines quite unrelated in a seemingly competitive field. Also it may be that most of the sales of one or more of the companies are to large customers such as mail-order houses, chain stores or wholesalers. Sales policies that the merged business would have to adopt might easily make volume or earnings or both, less than originally expected.

Merging Is Not a Panacea. It is all too easy to assume that, by combining several companies, great economies in many directions can be effected. But this does not always work out in practice. It frequently happens that expected savings are rather negligible in the final result. Often such economies as are realized are more than offset by new general administrative expenses which must necessarily be absorbed in the combined profits of the individual units. Well-intended centralized control of units sometimes amounts to interference with their efficiency and retards the development

of local talent. So I regard the proposed general administrative organization, and its probable cost, as a factor which should be given more serious thought than it often appears to receive in the present merger movement.

Economic soundness of a consolidation depends materially upon the economic soundness of its constituents and whether or not their relations with each other will be satisfactory. When a concern joins a merger it goes into partnership with all the other members. Each should consider the desirability of the others and whether or not they can work harmoniously together for the combined good of all.

Merging operations, well-conceived and capably worked out, are productive of a great number of real benefits and among them is one that I wish particularly to mention. The large enterprise arising from a merger is likely to have resources for organized research which the companies individually could not afford. The merged business, by retaining trained engineers, chemists, statisticians, market analysts and so on and having the work properly directed, becomes able to reach further and with a stronger arm, for the improvements essential to its progress.

Mergers, in themselves, are no panacea for diminishing returns on investment. Any concern entering one on a contrary theory is liable to be disappointed. Again, I believe that unless there is a sound reason for a merger and a sound basis—all plainly discernible in the form of definite prospective benefits—then the companies, in most cases, are better off if they operate independently.

Management. Next in importance to the factor of soundness is the question of management. Management implies leadership. Leadership includes acceptance of responsibility, coordination of effort, development of new ideas and ideals and the perfecting of organization not only in the large but in all its many details. The future of almost any consolidation depends very greatly upon the kind of management that it gets. The first year or two will, in all probability, be accompanied by many unusual problems requiring tact, resourcefulness and judgment. These are only a few of the qualities which we expect in the highest degree from good management.

First, the project must have a prospective executive head who not only has the knowledge and ability to direct the affairs of the combined group but also commands the confidence and respect of all the participants. I have seen proposed mergers fail for want of an able leader. Sometimes it is necessary to go outside the participating companies to find the desired executive head. The entire executive personnel should be considered, which means a selection of the best material for all the executive positions. It is not a matter of finding jobs for men but of finding and making men for jobs. Next, the management of the local individual units should be carefully planned, with a view to perpetuating each unit's successful operations. If any important executives or employees are to retire, it is important to know the reason for their retirement and gauge its probable effect on the future of the business.

Surplus Executive Talent. A merger of sound companies—whether or not the merger itself is sound—is very apt to create an embarrassing surplus of desirable executive talent. The question of what to do with these men is an exceedingly important one. If executive authority in a department be

divided, the possibility of inevitable friction will exist. If the surplus ability be carried along in such a way that friction will be avoided, the consequent overhead will reduce the economies that should result. The key executives in companies to be merged usually have groups of employees under them, doing responsible work. Some of these subordinates are affected by each selection made between two or more key men for one of the positions in the merger. If discord be aroused, one or more of the executives with their personal following may start a competing company or accept positions with competitors. While these troubles are controllable, they have many times led to undesirable results and should be recognized for what they are.

Surface Contradictions. In giving thought to the factor of management, we should not ignore that many corporations today, whose management and organization are not of the highest grade, are, nevertheless, strongly fortified and go forward from year to year with apparently satisfactory results. This seeming controversion of the importance of good management is often nourished by returns on valuable patents, established trade names or very fortunate holdings in basic materials; or even by a policy of manufacturing and selling staple goods at a ridiculously small margin of profit. There are various wealthy corporations, owned by families or small groups, with no market for the shares and little incentive to increase dividends. In many such cases, the management is able to operate without the alertness and the urge to improve its showing, which are enjoined under different conditions.

Financial Position. If a proposed merger appears economically sound from every important angle and is assured of thoroughly capable management, the next important factor to consider is financial position. The project should have the financial facilities and the backgrounds, which will enable it to exert itself to the fullest advantage. Its capital should be adequate, its working capital ample to meet the demands of its regular business and normal expansion and provide a satisfactory ratio of current assets to current liabilities. If, in the judgment of the sponsors of the amalgamation, some major expansion is probable, it should be provided for. If the project involves the question of assuming the unproductive assets or funded debt of constituent companies the extent to which this would be wise merits serious inquiry and study. The new business ought not to be burdened with such assets, debts, commitments, and so on that would in any way jeopardize its success.

Therefore, the financial position of each company under consideration for a merger should be determined and analyzed. Excess plant and obsolete facilities should be known, so that proper treatment may be accorded them. The merchandise inventories should be valued only on a basis which will result in a reasonable and normal profit when sold. Contingent liabilities, commitments, pending litigation and any contractual liabilities should be fully ascertained. It is usually desirable to have the properties of all the companies appraised by the same appraisers, as the valuation of assets should be consistent and on a uniform basis.

Earnings. The most important financial figures are those representing the earnings for prior periods. I mean not only earnings as actually shown by the books of the individual concerns, but also earnings as they would have been under the conditions that would have existed had the concerns been

operating as constituents of the proposed merger. If after such adjustment a concern shows no earnings and is not needed for some special purpose, it is generally a poor prospect for a merger. If the earnings have been on a downward trend, the reason should be ascertained; because declining earnings alone might make a proposed participant undesirable. Any extraordinary income and expenses should be carefully considered and possibly eliminated in determining the earning power.

The ratio of earnings to asset values, particularly fixed assets, serves as a valuable guide toward ascertaining to what extent, if any, excess plant facilities or other unproductive assets are carried by the participants.

Above all, the earnings of the individual concerns should be determined on a uniform basis; that is, the same policy should apply to all of them, with respect to inventories, depreciation, salaries, reserves, and so on.

Formula or Plan of Merger. After the determining factors have been considered and the merger is felt to be desirable, a formula or plan of merger must be worked out and agreed upon. This will indicate the proportionate value of each participant's contribution and the form of compensation that each is to receive. To find the plan that will be acceptable to all participants is frequently quite difficult. There is no pattern that can be generally adhered to. The formula obviously must be fair to all, should be developed in the light of all the factors entering into the determination of the relative values, so that the resulting basis of distribution to the previous owners will be accurate and just.

The formula will naturally be influenced by immediate requirements and by the plans for the future. If it is found necessary to raise cash through sale of securities to meet the conditions under which a merger is formed, expert banking advice is needed. In fact, no merger of any consequence should be undertaken without the guidance of a competent banker. Experienced judgment is required as to the market for the flotation of securities and the type which will be attractive to the investor and sound for the newly merged company. This question gives rise to others, such as having the securities eligible for listing on recognized stock exchanges.

It is apparent that before any proper plan of merger is attempted, the needs and desires of the participants must be known. With this information as a basis, it is usually possible to evolve a plan that will meet all requirements.

Discussing the Proposition. The principals who take part in merger discussions should approach the subject with a broad and open mind. Much will be gained if the atmosphere be clear of all prejudices, preconceived opinions whether favorable or unfavorable; if the first thought of every one be simply to see the proposition clearly in its major aspects. It is essential that each participant have the vision necessary to determine the benefits of a desirable consolidation and not give undue weight to minor factors. There should be a mutual willingness to appreciate the other man's point of view. No two businesses are exactly alike, and when we add to this the justifiable pride which each one has in his own property, it is apparent that if the work of consummating a merger is not leavened by a willing spirit of give and take it may well be impossible.

There is much to be said in favor of full and frank discussion between all parties. It enables every one to become properly acquainted with the proposition, and guards against misunderstandings, or lack of understanding, which is so undesirable and which in our experience has been a serious hindrance when final negotiations are about to be consummated.

Merger discussions call for breadth of viewpoint and judgment. A study of the successful combinations of the past, of which there are so many, provides ample illustration of the vision and resourcefulness of the men who made them possible.

Special Committees. It often happens that one company in a merger movement may be represented by an able financial executive who may comprehend the financial program fully and quickly. This may not be the case with the representative of another company, who may be an executive trained more in production, engineering or sales. Frequently, the course of the meetings has been simplified by forming special committees to study and discuss the various important phases of the program, each company appointing a separate representative to serve on each of the several committees. In this manner, means are afforded whereby each company can feel that it has received the benefit of all discussions which are so necessary in arriving at a clear picture of such an important proposition as merging one business with another.

However, there is no standardized procedure. What may seem most desirable in one merger may not have application in another. But this much can be said definitely: the participants should approach a merger with an open mind, reserving any advance objections until a reasonable period has elapsed for full and frank discussion.

Importance of the Budget. To combine detached businesses and combine them well, is a great deal more than any problem in arithmetic. It is a direct challenge to the keenest kind of judgment and foresight. Working out a merger should always imply that the elements of a sound operating plan are being conceived and developed. But this general plan in the minds of its authors is only a starting point. It must be rounded out and interpreted on paper, set forth in the form of carefully prepared estimates and schedules, as a guide to accomplishment and a medium for coordination and control. The management of a newly merged business must fix responsibilities, weld sales organizations, rearrange manufacturing, establish consistency of policy; in general, put its house in order to effect the purposes and economies expected. The management will have too much to do to have its work further complicated by the lack of well-ordered plan or budget of operations and expenditures or by any necessity for guessing about day to day and month to month accomplishment.

The budget, applicable as it is in all business, is indispensable in one newly merged. Under the budget plan, the scope and responsibilities of each department are clearly defined. The spending of money is governed by appropriations based on the aims and actual needs of the business. Production and buying are coordinated with sales in an orderly way toward the accomplishment of rapid turnover and the proper regulation of inventories, while the treasury department functions in the light of a forecast of cash to be

received and obligations to be met. By no other means than through an earnest attempt to establish and operate a budget, may management so quickly come to a realization that there are deficiencies in its form of organization or personnel, because successful budgeting depends so much upon good organization.

As soon as a merger is finally agreed upon, the first thought should be "budget." Obviously, the newly merged business will not be able to prepare its budget as accurately or as much in detail, as will later be the case. But despite this, it will be valuable, and as time goes on it should develop into one of the greatest single contributions to the company's success.

International Influences. It is safe to say that very few businesses are not affected by international influences today. Since the termination of the World War, foreign markets have taken an increasing volume of American merchandise and many of our leading industries have developed extensive international relations. This is really a great problem unto itself. No large enterprise would be built on a firm rock if 50 per cent or more of its production went to one customer or to one community. It has been predicted that the time will come when a business will not be considered sound unless it includes among its customers a substantial percentage of export trade to many different countries.

The question is indeed a factor to be considered in working out mergers. It calls upon the American manufacturer to study the habits, tariffs, laws and methods of foreign peoples. It requires him to understand the differences in labor conditions, overhead expenses and cost of raw materials abroad. Without a complete understanding and a harmony of ideals, business relations in foreign fields can be no more successful than they are in domestic markets approached haphazardly. Various companies are already establishing themselves in foreign countries through subsidiary companies, representing large capital outlays and requiring complete organizations.

It seems reasonable to believe that the time is not far distant when many such companies will find it desirable to create a market abroad for their securities, so as to benefit through ownership and the simplification of banking features involved. Certain European countries will always absorb a large amount of American securities. The listing of such securities on international exchanges should facilitate transactions of this kind; may even assist in popularizing locally the products of companies so listed.

POST MERGER ECONOMICS

BY THOMAS R. JONES, *Vice President and General Manager, Harris-Seybold-Potter Company*

Delimitation of the Subject. What economic possibilities lie in a new consolidation; what inherent difficulties lie in the way of economies; what economies are effected by the very fact of a merger; and what economies may

be brought about through a merger which cannot be brought about in the several constituent companies in their independent state?

The essential characteristics of a merger or consolidation "may be taken as the central control of a number of distinct and generally scattered operating units, most of which were previously independent concerns."¹ A merger may have been formed all at once or it may have been formed piece-meal, or it may have grown from a single parent business which has branched out into new fields.

The Reasons for Mergers. In the analysis of merger economies we may gain considerable knowledge of the possibilities for economies if we inquire into the reasons for mergers. If we find out why business men merge their industries we may see whether economies have any great place in the minds of those merging. If they have not, it is unlikely that the mergers will stand much chance in effecting economies.

A. Mergers for Economies. Many mergers are formed for the express purpose of internal economies in manufacture, distribution and administration. Not all of the mergers which are proclaimed to be made because of prospective economies are made for that reason. Too many other factors control. But it must be admitted, without argument, proof, or illustration, that such mergers do exist in substantial numbers.

B. Bad Conditions of Distribution. Greater than the factor of internal economy is that of elimination of bad merchandising conditions as a motivating force for mergers. An outstanding and successful merger of this type was one that took place in the paint industry. This particular industry was sectionalized, and highly competitive. The conditions may be pictured by the fact that this consolidation combined nearly fifty of these independent companies. All of the constituent companies retained their identities. Over a long transition period the individual trade-marks were changed gradually to one now nationally known. The major thought of this consolidation was not to combine plants, get quantity production and eliminate executive personnel but rather through the control obtained of the industry, indifferent average profits were transformed into earnings of fourteen per cent on the common stock.

A certain company in the machinery field paid five million dollars for a competitor which it once could have purchased for ten per cent of the amount and expected to lose in operating efficiency by doing it. The expected gain was not the possibility of a monopoly or even of economies—but to clean up a bad credit condition in the trade.

A survey by the National Association of Manufacturers showed that 79 per cent of 850 members regard price cutting as their major problem.

Charles F. Abbott, executive director, American Institute of Steel Construction, declares that lack of profits is caused chiefly by inefficient distribution methods that involve unfair, unethical practices; that anti-trust laws, in forbidding intelligent cooperation among business concerns, have expedited the formation of huge mergers, whose influence is to reduce competition.

¹ "Mergers in Industry," National Industrial Conference Board, New York, 1929.

Gordon C. Corbaley, president of the American Institute of Food Distribution, believes that the attitude of the Department of Justice toward the attempts of industry to put its house in order is unfortunate; that manufacturers must be permitted to control excess productive capacity in order to eliminate the destructive competition which he also sees as forcing concerns into huge consolidations.

Some mergers are forced through the necessity of controlling conditions of dealer distribution which have become unbearable. Some lines of men's clothing are now being sold through factory controlled retail stores. The history is this: Exclusive dealer agents became more and more exacting in demands. Prices, discounts, and terms were dictated under penalty of losing an outlet. Serious inroads were being made into the manufacturer's profits. The manufacturer bought some stores and started a chain to control his own outlets.

C. Smoothing of Sales and Production Variations. In businesses of highly seasonal character it is advisable to take on additional seasonal production but to choose the product so that the peaks of the one offset the valleys of the other.

The necessity of smoothing out sales peaks and valleys brings about strange combinations. The wedding of radio and mechanical refrigeration in several of our nationally known companies is probably the acme of such miscegenation.

D. Technical. A reason for merging which we rarely see advanced but which is primary and vital is that of increased possibilities for research. The whole case is stated in a clipping which I will quote verbatim:

First importance of chemical research in the synthetic textile fibre industry is shown in the merger of Tubize Artificial Silk Company of America with the American Chatillon Corporation, now being completed. *Consolidation is primarily to make possible more extensive research*, it also places under one head manufacture by three of the four chief processes now in use, and gives a spread and diversification in products not previously had by either company.

Textile and chemical engineers point out that the artificial silk industry is youthful and in a state of flux. A small army is engaged constantly in research to discover new methods of improving the fibre. Under such conditions, the research laboratory becomes the mainstay of the manufacturer who would not be swept out of business overnight. The small producer, with limited resources, is under a severe handicap. Hence mergers of this type, principally for research purposes, are inevitable.¹

Results in product development by General Motors Corporation with its General Motors Research Corporation and by the American Bell Telephone Company with its Bell Telephone Laboratories lay outstanding emphasis to this merger advantage.

A big match company forms an interesting example of another reason for merging—the utilization of byproducts. This company is not a true merger. It is a growth. It originally made only matches. Because it had

¹ *The Business Week*, May 7, 1930.

surplus lumber, the company established 40 lumber yards. This put it into the building supply business. Some of the lumber still left on its hands it started to make into toys and beehives. Beehives sell better with other bee supplies, so now the company is in the apiary business too. In an endeavor to produce an income from one of its cleared lumber tracts, it planted prunes, which put it also into the fruit business.

Du Pont similarly branched out. Duco, Rayon, Cellophane are all familiar trade names of products whose manufacture is based on gun cotton.

E. Management. A highly legitimate purpose in consolidation is that of making available a quality of management not to be afforded by a smaller company. In my opinion no company is too small for good management and I do not admit that good management is an economy available only in size. However, if good management is lacking and it can be made available by a merger, the merger is advisable.

We can scarcely imagine any economies resulting from a combination of soap, shoe polish and salad dressing. The Gold Dust merger was such a combination and in it were no economies of merging—a fact which its management admits. But there were economies in management. For example, one of the merged companies had an office of three floors of high rent space with four hundred clerks. These offices were closed, one floor was taken in a more reasonable part of town,—two hundred fifty clerks with several high salaried executives were removed. Without increasing the business, the business in this manner was made to yield a profit.

F. Personal. Probably the greatest, though least mentioned, reasons for mergers is the desire of executives to be big,—the desire to have increased opportunities against which they may measure their stature. The wish to beat the other fellow and the wish not to be out-classed are manifestations of this feeling. One who doubts that this factor is a big one in business, should recall the recent contests between various large New York corporations to have the tallest building in the world regardless of economies or costs.

Industrial mergers made for personal reasons may be unbalanced; may contain units having no relation to the whole.

G. Financing. Many mergers are pure promotional schemes—excuses for a stock-jobbing operation. A similar but more legitimate purpose is that of the attainment of sufficient size through combination to get a listing on some exchange and thereby create a broader market for corporate stock.

Diversification of product lends a valuable financial feature to a merger and often sufficient excuse for one. In my own company the profits of one division will often carry us through the losses of another. Total profits need be no greater but the fluctuations of the profit curve can be less violent. Profitable divisions of a company can put another division on its feet or carry it through a price war. New developments and new enterprises can be carried through to maturity by the momentum of unrelated and healthy divisions.

H. Miscellaneous. Fear is responsible for many a business merger.

In a town of 31,000 population there were four banks. Two of these banks suddenly merged. The other two banks—heretofore aloof competitors—through fear of possible consequences patched up their differences and came together.

In a certain equipment field there was a company doing about \$20,000,000 of business per year. It had almost a monopoly of a portion of the field and other companies in the remainder of the field were content to let matters rest. Suddenly the one company purchased a small and failing company doing a business in the remainder of the field. Because of fear of the intentions of this one company, three companies which heretofore had been at sword's points, came just as suddenly together and the one company had pulled the house down about its ears.

Some mergers are forced by the general trend of mergers and bigger business units. Outstanding examples of this may be seen in the realm of banking. Big businesses require big banking connections and the risks involved in small banks through carrying big business accounts are out of proportion to their abilities. This is one reason for bank consolidations.

If we scan carefully these many reasons for mergers, we will see that very few of the reasons have to do with internal economies. And if we will think carefully over many of the mergers we have known we will realize that they could not have come about because of large expected economies. If we study most of the results we will see that, if the economies of the merging were expected to show in greatly increased profits, something has happened either to the economies or to the expectations.

Please bear in mind that I distinguish between internal economies and external or trade economies which might be made through trade agreements. Moreover I distinguish between economies possible only through mergers and economies arising purely from management methods which could have been applied equally well to the constituent companies in their independent state.

Mergers Do Not Necessarily Bring Economies. There is a popular opinion current to the effect that all that a business has to do to increase profits is to become a part of a merger. This even goes to the point of believing that a group of red ink businesses can be put on a paying basis by merely merging them.

How can an overgrown industry avoid a shrinkage or a loss by the simple process of merging the units of the industry? Or how can one add two and two and two and get an answer less than six? Mergers *per se* do not nullify economic law; they do not change one whit the elements of mathematics; they do not do the impossible, despite the popular opinions to the contrary.

The National Industrial Conference Board made a study of forty-eight successful consolidations over a period of fifteen years. Only those corporations were included which were organized through an amalgamation of several theretofore independent and competing concerns, only those corporations whose fields of operation were national in scope were included and only those corporations were included on which information was adequate for at least ten years. Forty contemporary similar consolidations which went into bankruptcy or were forced into financial reorganization were cited.

The forty-eight successful organizations showed that (1) their rates of earnings on capital and surplus did not increase subsequent to the consolidations, in fact, over a period of fifteen years, they actually decreased slightly; (2) the rates of earnings were not as much as would be expected from any well managed independent; and (3) the variations and earnings resulting from

the fluctuations of the business cycle were comparable with the fluctuations of general business.

As a result of these and other findings the research staff of the board concluded:

First, when whole industries have been subject to stagnation, the mergers have been unable to escape the prevalent drift toward ruin. On the other hand, the abnormal growth of new industries has provided such a favorable situation for business enterprises that the mergers have participated in the general prosperity. In the second place, industrial consolidations have not been able to avoid sharp decreases of profits in years of general business depression. They have been affected like other enterprises by the falling off of the demand for their products resulting from business maladjustment. Third, when the consolidations have been handicapped by an unmanageable financial structure, which subjected them to fixed charges above their minimum earning capacity, they have been unable to adapt themselves to new situations or to take advantage of new opportunities and have thus forfeited their industrial leadership. Finally, and this is the most significant conclusion to which the data surveyed point, business mergers offer no substitute for competent management. Consolidations are as dependent as other business concerns upon the sound business judgment and clear foresight of their executive management. Certainly it is not too much to say that the combination movement has not "discovered" a royal road to profits. It has not introduced a revolutionary principle of business organization, which renders antiquated all the alternative expedients for controlling the direction and pace of industrial operations. It has not provided an instrument for profit-making so effective simply from its own structural characteristics as to emancipate business executives from the necessity of cultivating those traditional requisites of success in industry: prudent investment, sagacious management and technical ingenuity.¹

Reasons Why Mergers Tend to Be Uneconomical in Operation. Merging, as such, not only does not guarantee economies but the merger brings about some conditions which, if not combated wisely and vigorously, will work in exactly the opposite direction.

Let us assume a merger which will not permit of plant and organizational consolidation. We will assume that the organizations of the constituent companies are efficient and not top-heavy. Here are our organization charts:

Now under the consolidation, if the red-tape-delays and general mismanagement incident to centralized control are to be avoided, it will be necessary to maintain a complete organization at each company. If the former organ-

¹ "Mergers in Industry," National Industrial Conference Board, New York, 1929.

izations were efficient and at a minimum for pre-merger purposes then the fact of a merger will not reduce them. But it will be necessary to have a super organization for the control of the merger. The organization chart will now look like this:

And the men in this added and superimposed organization receive far higher salaries than those in the lower strata and it will take considerable and drastic economies to offset the heavy super overhead.

Furthermore, the directing heads are farther away from their operating problems than were the former heads of the constituent companies and this is a fact which will need some offsetting economies.

A merger is apt to precipitate a decided *let-down in morale in the second stratum of executives* in the constituent companies. Those who have done mountain climbing will remember how, after the first seven or eight hours of climbing, one feels that he is nearing the top and fastens his eyes on a peak ahead, certain that that is the goal. Another hour of muscle-torturing and lung-racking climbing and he reaches this objective to find that the peak is only a shoulder on the route. Three of these disappointments in as many hours have stopped many a climber and turned him back before his goal was reached. This same effect is had when additional organizational peaks loom ahead of the executive who finds that the peak toward which he had been aiming turns out to be a shoulder.

A drop in morale is not necessarily confined to the secondary executives. Owners and active officers in a successful business are apt to feel that a merger ends their troubles, that they may sit back and let some one else assume their burdens.

Mergers are apt to bring about the committee form of government. This may be disastrous. I cannot point to a single large business, started from scratch and built to a position of dominance which was brought through by a committee system. Some one must have the final say,—the sole responsibility.

the fluctuations of the business cycle were comparable with the fluctuations of general business.

As a result of these and other findings the research staff of the board concluded:

First, when whole industries have been subject to stagnation, the mergers have been unable to escape the prevalent drift toward ruin. Let us assume a merger which will not permit of plant and organizational consolidation. We will assume that the organizations of the constituent companies are efficient and not top-heavy. Here are our organization charts:

Now under the consolidation, if the red-tape-delays and general mismanagement incident to centralized control are to be avoided, it will be necessary to maintain a complete organization at each company. If the former organ-

¹ "Mergers in Industry," National Industrial Conference Board, New York, 1929.

izations were efficient and at a minimum for pre-merger purposes then the fact of a merger will not reduce them. But it will be necessary to have a super organization for the control of the merger. The organization chart will now look like this:

And the men in this added and superimposed organization receive far higher salaries than those in the lower strata and it will take considerable and drastic economies to offset the heavy super overhead.

Furthermore, the directing heads are farther away from their operating problems than were the former heads of the constituent companies and this is a fact which will need some offsetting economies.

A merger is apt to precipitate a decided *let-down in morale in the second stratum of executives* in the constituent companies. Those who have done mountain climbing will remember how, after the first seven or eight hours of climbing, one feels that he is nearing the top and fastens his eyes on a peak ahead, certain that that is the goal. Another hour of muscle-torturing and lung-racking climbing and he reaches this objective to find that the peak is only a shoulder on the route. Three of these disappointments in as many hours have stopped many a climber and turned him back before his goal was reached. This same effect is had when additional organizational peaks loom ahead of the executive who finds that the peak toward which he had been aiming turns out to be a shoulder.

A drop in morale is not necessarily confined to the secondary executives. Owners and active officers in a successful business are apt to feel that a merger ends their troubles, that they may sit back and let some one else assume their burdens.

Mergers are apt to bring about the committee form of government. This may be disastrous. I cannot point to a single large business, started from scratch and built to a position of dominance which was brought through by a committee system. Some one must have the final say,—the sole responsibility,

A merger causes a *shifting of jobs*, the placing of men into work with which they are unfamiliar. In the changing of jobs, and the mingling of the personnel of the unit organizations, there are bound to be many unpleasant personal contacts. Extremely cautious and skillful guidance is necessary on the part of the chief executive in order to avoid the losses due to these eddy currents.

Administrative economies are often foremost in the claims made by the promoters of a merger. Yet these advantages frequently prove fallacious. It is true that when several rather small units are brought together through a merger administrative economies are usually possible. When a vertical merger is arranged surely all administrative expense connected with the buying and selling departments of the intermediate links in the chain may be eliminated.

Generally speaking, however, too much has been expected in the way of cutting down administrative overhead. Of course if poorly managed businesses are brought together the same efficiencies as would have been possible anyway should be made effective. But the hope of cutting down markedly on the general clerical force usually proves to be poor economy when more carefully studied. And the salaries and perquisites of the managing executives can rarely be reduced without a marked lowering of executive morale.

It has proven to be the rule rather than exception, however, if my information is correct, that when well managed units are brought together into a well conceived and properly controlled combination the administrative expense is increased rather than lessened, due to the need of additional compensation for men who are being given heavier tasks and due to the need of more elaborate accounting and statistical control operations by which the larger operations of the combination must be appraised.¹

Add to the above the necessity in many mergers of providing policy jobs for some of the heavy stockholders in order to get their consents to the merger and we can see that the personnel factor looms large as a rock on which the merger ship may become wrecked.

Losses Incident to Effecting Economies. *A. Drop in Total Sales.* One aftermath of the merger of companies making identical products always seems to give the management extreme surprise and pain,—this is the fact that the sales of the merged company, unless some unusual factor intervenes, are always less than the sum of the sales of the independent companies before merging. This is logical when one stops to think of it. There are always some customers of one company that are customers because they do not like some other company. In the case of a merger these customers of both companies are liable to go to competitors. One company which purchased a second estimated a 30 per cent decrease in sales of the purchased company and so far their estimate seems to be about correct. Another reason for a drop in sales is that in an attempt to economize on selling expense insufficient attention is given to the proper balancing of the sales force. One company which produces mechanical equipment purchased another company which made a different equipment for the same purpose. The first company was in control of the consolidation and, to realize sales and engineering

¹ VISSCHER, O. W., "Some of the Conditions Which are Bringing Forth Mergers," General Management Series, No. 103, American Management Association, 1929.

economies, released practically all of the salesmen and engineers of the purchased company. The management did not stop to think that their own salesmen and engineers were schooled to their own product and naturally felt it superior to anything else on the market. The results were that the sales of the purchased organization after two years had dropped so that the total sales were only slightly in excess of the sales of the first company before the purchase. Only drastic action and reorganization by a new management started the combination in the proper direction.

Much in selling is a result of the personality of the salesman. Consequently a salesman usually carries some of his customers with him. A group of salesmen, released in the interest of economy and hired by competition will also affect the total sales.

B. Excess of Assets. C. New Investment and Moving Expense. A consolidation of three companies for various reasons failed to make, by 50 per cent, profits which were made by the constituent companies previous to the merger. One of the factors had to do with excess plant capacity and a wide separation of plants and consequent lack of effective control. It was deemed necessary to consolidate plant operations in order to get all of the economies that were possible. To do this involved a write-off of \$700,000 from the assets as the abandoned plant was in a location where it could not be sold for its book value and an expenditure of \$190,000 for additional plant and for moving. The plant write-off amounted to 10 per cent of the total assets and approximately 30 per cent of the net worth. The expenditure was deemed advisable because it would be returned in savings in a very short time and the company decided it would rather have earnings than book assets.

In order to realize the savings possible from another merger it was necessary to abandon completely one foundry, build an entire new one and revise an antiquated power plant at a total expenditure of over \$1,000,000. While the entire expenditure was returned in two years, the process of going through such an outlay was necessarily nerve racking.

A company purchased and merged other allied companies from time to time. It thought that it could economize through making one product or a part of one product in each plant and thus get greater quantities to work on and reduce manufacturing costs. It had a foundry in which it concentrated its castings. All plans were carried out as scheduled but when the end of each year rolled around profits failed to appear. Why? Sales were maintained, but it was found that each plant had about as much overhead as it had had before, a large administrative overhead had grown up and the trucking charges between plants were unexpectedly high. There was but one answer. The firm built a very large new plant, abandoned all of its old plants, made one overhead grow where several had grown before, eliminated the interplant trucking, bought new equipment and in 1929 after writing off all moving expense made a profit of \$300,000.

The prosperous coal companies know that if they purchase less prosperous ones economy will demand that the less efficient mines be shut down. This will mean a direct write-off of assets or a considerably decreased percentage of earnings on the investment and the coal companies do not see why they should play angel to this extent.

D. Inadequate or Top-heavy Organization. Some economic chickens counted before they are hatched are those of the possible savings through centralization of administration. There is a limit to which centralization can go and beyond this a centralized organization becomes unwieldy. Emphasis was given to this by a large grocery chain which was forced to dissolve its central control into district controls to the consternation of some five hundred employees in the central office. In the reorganization the general office is practically eliminated. The branch managers will buy as well as sell. Even accounting is decentralized in this swing of the pendulum.

Another case involved the sales, engineering and production divisions of a company. In 1921 to 1922, during the postwar slump, the machine-tool industry was especially hard hit due, not only to the large excess capacities resulting from the war work, but also to the large amount of excess equipment on the second-hand market—most of it nearly new. The situation was disheartening and, to help to fill a very empty plant, one manufacturer looked about for additional products. He purchased a flourishing, though small, business which made and sold a machine tool, though one requiring an entirely different design, sales method and technique. In order to realize the economies desired and to help absorb an excessive overhead in his own plant, this manufacturer eliminated practically the entire overhead from the purchased company, and retained only five or six people.

Matters dragged along, and for some reason the new division of the business did not flourish. Sales lagged. Complaints came in from the field. The product gained the reputation among customers of being third rate in contrast to the first place held by the standard product. Despite the reduced overhead, every machine shipped took with it part of the profits of the standard line.

The management became desperate and finally decided on desperate measures. A plant was purchased, an experienced engineer was brought in from the outside, a brand new organization was built up and the two products—of similar nature, sold through the same channels and to the same customers—were made and sold as though owned by separate corporations except that general policies were the same. Within two years the new product was the leader in its field, sales rivaled those of the old product and profits exceeded those of the parent company. But not one cent was saved in overhead, in fact, it was nearly doubled.

E. Development Expense Necessary to the Realization of Engineering and Manufacturing Savings. One of the large savings which can be made in similar products is that of standardization of parts because of the various sizes and varieties of product so that while a large variety of product may be made, parts may still be made in quantities. Here again is a heavy initial cost of realization. The engineering and development, new patterns, jigs, etc., incidental to such a program are extremely expensive.

Possibilities for plant consolidations loom large in many prospective mergers. Possibilities of rearrangement of production so that merged factories may specialize on one or a few products also form desirable sources of savings. But not all is rosy. Product, machinery, patterns, and parts must be moved; plants must be replanned; organizations must be trained to new

products; redesign for standardization with all of the changes in patterns, tools, and layout which accompany redesign.

The cost of these changes compared to the profits of the first two or three years of a merger or to the economies which may result are oft times startling.

F. The Problem of Excess Personnel. A serious problem which the management of a merger has to deal with is that of surplus personnel. The most outstanding example of the intelligent handling of such a condition is that of the U. S. Rubber Company.

One may be faced with the problem of releasing a group of approximately two hundred fifty men, some of whom have been with the company for as long as forty-three years. The process of going through such a move is extremely nerve-racking. Judged from a purely humanitarian angle it is unfair to the people released. Some people seem to feel that the employees of a purchased company demand no more consideration than the victors in ancient warfare accorded the captured enemy. But a new management assumes the responsibilities of the old management, and from the standpoint of the employees the new management is merely a phase of a continuous phenomenon and not a change of employment. Age of service demands consideration and it may take an additional cash outlay to discharge the obligations to affected personnel.

G. Excess Financial Structure. Several elements lend to an excessive financial structure. Prices paid for the various businesses entering a merger may be based on the earnings of peak years which may be mistaken to indicate a trend. The owners of the constituent companies may each hold out for an advantage with the result that the total capital structure of the consolidation is too high. Adjustments of stock values in arriving at figures for interchange of security values usually trend upwards instead of downwards. Excessive promotion profits, commissions, and bonuses water the capital structure. Also all of the weaknesses of each independent company are added together and, if there are any inherent weaknesses in the merger, the total will assume larger proportions. W. R. Angell, vice president of Continental Motors, has drawn this picture for us:

If several successful independent companies are merged on the usual formula, the public purchasing the new shares pays an enormous price for duplicated good will, duplicated dealer organizations, and duplicated plant capacity, machine tools, inventories, dies, designs, etc., all appraised at reproductive values. These burdens, loaded upon the shoulders of the new company, generally more than offset the advantages hoped to be gained through unification of effort.

H. General Comments. The first two or three years of a merger are the hardest, and those who are proposing mergers for the purpose of economies must look this fact coldly and fearlessly in the face.

Heavy outlays of cash are made to make possible the realizable savings, drastic write-offs in fixed assets; organizations must be carefully welded together, guided and directed; it may be necessary to suspend dividends and profits may show at a very disappointing figure. The heavy and courageous write-offs of assets necessary to realize consolidation economies in the first year or two of a merger, suspension of dividends and reduced profits are more

than most new managements wish to shoulder responsibility for. The alternative is to carry dead assets on the books and decide to show low earning percentages with no justification for additional expenditure or no profits until the abandoned assets have been completely written off.

Prospectuses gotten out by financial houses show possibilities for increased earnings through mergers but I have yet to see a prospectus which brought out the amount of punishment which the management and stockholders first must take if these savings are to be realized.

Economies to Be Realized through Merging. Lest what has gone before will lead to the assumption that consolidations are unprofitable and undesirable things, let us look for a few minutes on the other side of the picture. We have been talking largely about internal economies, but mergers can be profitable without internal economies as I have already shown in several cases. They can be profitable because of management possibilities and they can be profitable in many instances because the merger itself will afford economies which are not otherwise possible.

Production Economies. A. Identical Products. Where companies making identical products have merged the first and most obvious saving is that available through plant consolidation. Plant consolidation alone is insufficient. This should be followed by the elimination of product variety which will involve a large amount of redesigning. It should also include standardization of product leading to a maximum of interchangeability of parts and units. If the foregoing recommendations are impossible and it is necessary to make two complete lines of product, although this condition is rare, it is possible that large overhead savings will be precluded by the complication of shop system, the consequent possibility of delays and the increased production control organization necessary. Also, such a consolidation will often result in the necessity of a new shop layout.

B. Similar Products. Where similar but not identical products are involved in a merger, plant consolidation will reach maximum effectiveness only if the parallel products are redesigned so that they can use interchangeable parts and units. In many cases because of complications arising through plant consolidation it is advisable to carry out a program of plant specialization. In this case one plant may be made to make one portion of the product while another makes the remainder and does the assembling. For example, two companies manufacturing different types of printing presses might make all of the press feeders in one plant and all of the printing mechanism in another. Such a program of specialization involves a relay-out of the two plants and the moving of machinery and equipment.

C. Unlike Products. Mergers of manufacturing plants manufacturing unlike products present great difficulties in realization of manufacturing savings. Sometimes waste products of one plant may be used as raw material in another. In the case of a vertical merger, obvious savings may be made in reciprocal adaptations of product to the end of mutually reduced costs.

D. General. In many cases of consolidation of production there are always some possibilities of the consolidation of indirect functions. One executive, for example, may direct several production planning divisions. Consolidation of equipment also represents a source of savings in the event of

plant consolidation, as partially idle equipment in one plant can often be put to continuous usage on combined products. Plant consolidation should not overlook the possibility of availing itself of the cheapest labor, least taxes, and best transportation conditions. In any case, one should advance the warning to beware of too much centralization. This is the rock which has sunk many a ship in the sea of red tape.

Administration Economies. Ofttimes savings can be made in the administrative end of the business. However, the administrative field is not always the prolific source of savings that it is expected to be. This I have pointed out elsewhere. The advantages in the administrative end are often the intangible ones. Diversification of product leading to greater stability of business, the possibility of more intensive research and the advantages gained through savings, such as flexibility and the possibility of carrying through development programs, and the advantages of quantity purchases usually mean more than the savings due to direct cuts in administrative overhead.

Sales Economies. Savings in the sales departments are apt to be small. Savings having to do with sales usually come through the stabilization which may be obtained in the industry in general and the elimination of price cutting and long-term credits. The possibility of leveling sales peaks is not to be overlooked. Ofttimes a consolidation is necessary to get the proper control of dealer and jobber outlay. However, this is something to be undertaken with a good deal of prayer for the reason that it is difficult to control permanently any outside organization, without enlarging the opportunities for a small or new competitor. The possibility of price fixing through a merger is apt to have boomerang tendencies. There are very few mergers which in the past have attempted price cutting and were permanent successes without a drastic change in policy.

Management, the All-important Consideration in Merging. The merger with its large size, and diversified ownership, will develop the demand for the professional manager in contrast to the owner manager of the independent company. And, as before brought out, scarcity of supermanagerial brains may, in itself, be sufficient justification for a merger.

George K. Morrow, manager of the United Cigar Stores makes this statement:¹

There do not have to be any "economies of merging." The only need is that a company be given a business management. The latter doesn't have to have any relationship to the first, either in product or market. What we give them all are economies which most people haven't the courage or knowledge to put through.

A large machine-tool consolidation of many years standing was having but indifferent success. One division in particular was losing \$100,000 to \$125,000 every year. This division was sold to another company—a company which made heavy machinery and knew very little about machine tools. Under the management of the new owners this division produced a profit of \$600,000 the second year of the new control. Some of the economies made in this case could not have been brought about without a merger but the first merger without management failed to produce them.

¹ *Business Week*, May 7, 1930.

An Example. Now that we have gone this far it might be well to see how all of the factors which have been discussed have applied to a representative merger. The one that I have chosen for presentation is a very large company; the name and reputation is widely known. Every factor which can be favorable to a merger has operated in this case. The management is of the best. The board of directors consists of more than a score of men nationally known as keen business men. The industry in which it operates is basically sound. Competition is keen but high class and fair. The products of the company are diversified over the entire field in which it is operating. It is the largest company in the field, but it has no line of product which does not meet with keen competition from a competitor. Some twenty-seven companies not including more than twenty sales subsidiaries are represented in the merger. The conditions under which the final merger was brought about and consummated were about as favorable as ever attained in the case of mergers. In the face of all these facts let us see what has been accomplished in the first three years of consolidation.

There were originally thirty-five manufacturing plants. This has been reduced to twenty-seven which is a total reduction of 23 per cent. In making these accommodations the consolidation was wholly made in the direction in which labor was cheaper and other manufacturing economies could be effected. The number of factory employees has been reduced 15 per cent in the face of an increase of 15 per cent in factory output. The number of branch sales offices has been reduced from 550 to 250 with a wider representation than was had by the constituent companies.

Here is a significant fact which bears out some previous statements. In spite of the reduction of over 50 per cent in the branch offices, sales forces were not reduced by one man although they were reorganized. Duplication of departments was eliminated; the accounting and executive personnel alone were reduced by more than three hundred; all engineering departments and development laboratories were consolidated. Office forces were reorganized; factory readjustments made and all obsolete equipment abandoned. Within this period of time it is felt that most of the merger economies have been realized although there are probably considerable economies yet to come.

We would consider that with these indications of a vigorous and intelligent management profits would have been greatly increased. What actually happened is this: In the year immediately subsequent to the merger profits were cut in two. During the last fiscal year, which was pronounced by all competitors as being exceptionally good in which all reported record-breaking earnings, the earnings of this consolidation were about equal to what they were in total for the constituent companies in the year previous to the consolidation. During this time the total financial position is not greatly altered. By this we mean that the current ratio has remained practically constant as did the net worth. Dividends were paid on the preferred stock but only one dividend was paid on the common, although the directors believed that the company was on a permanent dividend paying basis. Total surplus accounts remained constant in spite of the fact that all earnings possible were plowed back into the business. A detailed examination of the financial statement will show considerable advances made in that some of the capital structure

has been reduced. It is rather significant that twenty-five per cent of the total assets is goodwill and patents. The company has a very heavy financial structure, which is many times the case with mergers.

It is patent that the foregoing example shows very clearly that merging does not automatically mean economies. As I studied the report on which these figures are based I had a deep sympathy for the long hours and hard work put in by the management in bringing this organization under control.

Of course this study is somewhat unfair to mergers in general in that it does not cover a sufficient period of time. I believe that this company is going to show decided profits in the future, and that these profits will arise out of economies. However, I am not at all convinced that the economies could not have been effected in constituent companies.

Summary. In summary let us keep three things in mind. First, the subject of this paper implies a consideration of internal economies through merging; second, there is a distinction between external and internal advantages and economies in merging, both of which may lead to more profits; third, there is a distinction between economies which are made as a direct result of a merger—which could not have been made in the constituent companies in their independent condition—and the economies realized through a merger because of improved management—management which could have been applied to the independent companies.

It is by no means a general rule that mergers make big earnings; many of them do not make even the sum of the earnings of constituent companies; many mergers are made with no thought of economies arising from the merger *per se*; there are many forces in a consolidation which militate against economies or which tend to create losses which offset economies; a well-designed merger achieved under certain proper conditions can make more money than the unmerged independents; but merging is not a substitute for management, and management is the first and most important consideration.

Not one thing which has been said must be construed to decry all mergers. I merely point out and emphasize that, from the viewpoints of the management and economics not all is gold that merges.

Mergers will continue as long as the ambition of man continues. Mergers have justified themselves beyond all doubt when carefully and impersonally designed. The size of mergers will be limited only by the limits of man to control them and we have not reached that limit yet.

A merger should be more than an ill-advised monument to a man's ambition or a mere stock-jobbing proposition.

A consolidation, to justify its existence as a consolidation, should accomplish things which were impossible to accomplish in the independent businesses of which it was constituted. It must produce:

1. A better product at the same price or the same product at a lesser price.
2. More stability in the industry.
3. More profit for the investors.
4. Greater advance in the industry.

and, if it is successful it will have been made up of a grouping of successful businesses on a sound and conservative capitalisation, with adequate resources, competent personnel, and *will have been based on management.*

CHAPTER VIII

DEPRECIATION AND OBSOLESCENCE¹

BY HAROLD VINTON COES, *Manager, Industrial Department, Ford, Bacon and Davis, Inc.*

Webster defines depreciation as "the act or state of lessening worth." According to this definition all lessening of worth, whether due to age, wear and tear, lack of proper maintenance, decrepitude, inadequacy, or obsolescence, can be termed depreciation.

H. A. Foster, in "Engineering Valuation of Public Utilities and Factories," states that

. . . at the time of an appraisal all these forms of lessening value have to be given consideration as depreciation, but from an accounting standpoint, depreciation is only that deterioration of an object that cannot be made good by repairs, but requires a complete renewal. Obsolescence, inadequacy, and supersession, being speculative and prospective, play no part in this form of depreciation, and all other deterioration is to be made good by maintenance and is so charged on the books.

The Illinois Manufacturers' Costs Association makes this statement with regard to depreciation:

Depreciation is due to possession and use; it is a decline in the value of all fixed assets—land excepted—and impairment of capital which is certain to occur as a result of deterioration through lapse of time, wear and tear, or obsolescence.

The main purpose of the depreciation charge is not to show values on the balance sheet, but to apportion to the several accounting periods the net outlay of capital represented in the assets that are being depreciated. This actual charge may leave an amount having little relation to the physical valuation of the assets at a particular date and to one interested only in valuations the charge may seem a fiction, but successful business management has found it to be the only safe and sound principle to follow.

Definition: Brief definitions of some of the terms just referred to may help us to a clearer understanding of the subject.

Decrepitude. An article, building, equipment, tool, fixture, or the like may become so old and worn that new parts can no longer be retained in place by the original body, and hence the cost of maintenance becomes so high that it is cheaper to replace the article.

¹ Reprinted by permission from *Mechanical Engineering*, vol. 51, pp. 342-344, May, 1929.

Supersession or Inadequacy. Foster defines this as "that lessening in value which takes place by reason of the growth of business, rendering apparatus inadequate for its purpose and compelling the installation of machinery capable of greater output of capacity."

Obsolescence. This is usually that lessening in worth which is brought about by developments, inventions, and changes in the art that render a plant, any part of its equipment, or whole sections of it, uneconomical of use as compared with newer types available of greater efficiency.

The Century Dictionary defines obsolescence as "going out of use," which definition represents a falling off in the value of usefulness of a thing from causes outside of the thing itself as distinguished from the effect of wear or physical deterioration.

Wear and Tear. This form of depreciation and the one regularly recognized in accounting practice is that due to the elements, to abrasion, accidents, accelerated usage, and the like. Roofs can be repaired, glass replaced, new bearings installed, slides planed down, and bushings replaced; and such deterioration and its correction through replacement is usually charged to operating expenses. Experience has shown that where obsolescence has not set in or is operating, and facilities are kept in reasonably good operating condition for the work that they are called upon regularly to perform, they are then maintained at from 80 per cent to 85 per cent of their original functioning condition. There are buildings in Europe that are in good condition, yet several hundred years old. We, all of us, have seen Corliss engines in operation over fifty years old. Some kinds of standard equipment, such as certain types of machine tools and textile equipment, are still good today, in many instances, for the purposes for which they are used, even though they may be forty to fifty or more years old. Some of these facilities actually depreciate very little from age, use, and wear and tear, yet they have to be replaced on account of obsolescence rather than from decrepitude or wear and tear.

The Federal Income Tax Regulations state:

The necessity for a depreciation allowance arises from the fact that certain property used in the business gradually approaches a point where its usefulness is exhausted. In the case of tangible property it applies to that which is subject to wear and tear, to decay, or decline from natural sources, to exhaustion and to obsolescence due to the normal progress of the art, as where machinery or other property must be replaced by a new invention, or due to the inadequacy of the property to the growing needs of the business.

Obsolescence. With respect to physical property, the whole or any portion of which is clearly shown by the taxpayer as being affected by economic conditions that will result in its being abandoned at a future date, prior to the end of its normal useful life so that depreciation deductions alone are insufficient to return the cost (or other basis) at the end of the economic term of usefulness, a reasonable deduction for obsolescence, in addition to depreciation, may be allowed in accordance with the facts obtaining with respect to each item of property . . .

Deterioration and Obsolescence the Two Prime Factors of Depreciation. Depreciation, then, is made up of two prime factors, deterioration and obsolescence, and they do not run concurrently in any given case, for which-

ever of the two is operating the faster, governs. A given type of standard machine tool may last fifty years at its present usage rate before it can be no longer commercially repaired. That would be depreciation at the rate of 2 per cent a year. It may, however, become obsolete two years after it is purchased for the purpose for which it was secured, and the rate, if such it can be called, would be 50 per cent a year.

No Accurate Rate of Depreciation Determinable. Accounting practice requires a rate for depreciation in order to show the depreciated value of the assets on the balance sheet and in the accounts of the business, and yet it is well recognized that there may not be any close connection, as stated by Dicksee, an accounting authority, between the intrinsic value of capital assets at any given moment and the depreciated value at which they appear in the books of account. Depreciation rates, however, are estimates only, and by the very nature of the many variable factors these rates must be set arbitrarily, so it can be said at the outset that there is no such thing as an accurate rate of depreciation. Climate, location, usage, care, promptness in the character of the repairs, the original quality of the article, and its condition at the time of acquisition, all have a bearing on the ultimate life, obsolescence excepted. These factors all compound in different proportions under given conditions. Since there is not a sufficient amount of data for any given article, under diverse conditions, to be able to treat the subject on an actuarial basis, the accrued depreciation must be the best estimate of those best qualified by experience and judgment to establish it.

Obsolescence is a form of depreciation that infrequently can be accurately estimated in advance of its definite occurrence. Confused thinking on the part of accountants, engineers, and the taxing bodies has rendered it difficult for executives to consider intelligently the problems incident to it and to provide some means for financing those operations that are suddenly required by reason of the immediate occurrence of obsolescence.

The Illinois Manufacturers' Costs Association, in its pamphlet on depreciation, has this to say about obsolescence:

Obsolescence is recognized as the most difficult element to determine, pertaining to the depreciation charge. In its determination, management not only has to make a guess as to the future of their own business, but as to what inventions will be made in the course of the next few years. However, past history teaches us that obsolescence has discarded more fixed assets than wear and tear.

They go on to comment on the practice of capitalizing obsolescence, and remark that the policy of capitalizing the unabsorbed depreciation of a superseded asset by adding this to the capital invested in the new facility, is not only unsound from an accounting viewpoint, but if persisted in will produce such an inflated investment in fixed assets that they will be carried on the books far above even replacement costs, in a period of higher prices. This must not be confused, however, with the case where an improvement and rehabilitation has been made of the existing facility that renders it of greater value for the purpose at hand than previously reposed in the reconditioned asset.

Causes of Obsolescence. Machines, equipment, methods, and processes become obsolete for many reasons:

1. An extensive change in the method of manufacture has developed.
2. A substitution of materials is to be made.
3. A substitution or consolidation of operations may be desirable.
4. Newer machines of the latest type will produce the same part or piece more economically.
5. A newer machine or method may reduce:
 - a. The hazard to the operator.
 - b. The hazard of fire.
6. To reduce waste and spoiled parts, more rigid and heavier equipment may permit heavier cuts or drafts and produce better finish or give greater required accuracy.

In certain cases it has been possible to go back and study the life history of a property, facility, or group of facilities, and determine when and how and over what periods obsolescence has been the governing factor of depreciation instead of deterioration, in the retirement of the property prior to the expiration of its estimated normal useful life. The studies are complicated and difficult to make but are informative in formulating policies to provide for future contingencies. They are no guarantee, however, that similar conditions arising in the future will bring about the same results in the same periods.

When we realize that the railroads spent nearly \$35,000,000,000 in the period from 1922 to 1927 to improve their means and methods of transportation; that the automobile industry now produces ten cars per man in the time formerly required for one; that 2 men do the unloading work of 12 in the steel industry, 2 men the work of 14 in furnace charging, 7 the work of 60 in pig casting, and in the open-hearth operation 1 does the work of 40, and in pig-iron unloading 2 do the work of 120, as pointed out by Messrs. Simonds and Thompson in their book "The American Way to Prosperity," then we begin to comprehend the part that obsolescence has played and is still playing in the industrial drama.

Obsolescence, then, is the most troublesome factor in depreciation today and is giving executives more concern than deterioration since it is not adequately provided for in most instances. The more progressive companies charge the deterioration factor of depreciation, either through machine-hour rates or the factory overhead, direct to the cost of the sales, and endeavor to secure in the price levels proper allowance for depreciation for every saleable unit of product turned out and sold. This is not true, however, of the factor of obsolescence, since this, like a fire, to all intents and purposes, occurs without warning. To guard against a loss from this source (fire) we use fire insurance, where the risks are spread and the burden per individual lightened. It is believed that it is entirely reasonable to assume that in the majority of cases, except in certain public utilities and a few isolated cases in industry, the price level is too low on the average to permit an adequate recovery of the assets wasted by reason of the factor of obsolescence. Now this is a serious menace to industry and to the future of industry in this country.

Two Sound Ways of Dealing with Obsolescence. How can we cope with this situation? There seem to the author to be two sound ways to deal with this problem, since it is patent that we cannot set up a rate for obsolescence in the majority of instances that means anything. These are:

1. Set aside from surplus net earnings a definite amount based on such past history and experience, and appraisalment of the future, as best judgment in each case will permit, and actually create an obsolescence fund whose rate of upbuilding may vary from year to year, depending upon the business and the surrounding conditions—the fund not to be subject to dividend declaration except after a careful review of all factors affecting the immediate and future position of the company.

2 For industry to consider careful cooperation with the insurance underwriters with a view to working out a basis of insurance for obsolescence, just as for fire, spreading the risk and lightening the burden per individual.

In the first case we should be carrying our own obsolescence insurance; in the second case it would ultimately be done on a more scientific and equitable basis, and the cost of the premium would be included in the cost of sales. Admittedly, there are difficulties in working out obsolescence or placing it on an insurable basis, but it does not seem to the author that the problems presented are any more difficult or of greater magnitude than those which confronted the insurance underwriters when other risks and hazards were placed on an insurable basis.

The all-important thing for industrial executives to bear in mind is that no one is immune from obsolescence, and that furthermore the lack of a definite appreciation of this fact and a comprehension of what it may mean in the mere matter of economic existence is responsible for price levels now too low to permit, in too many instances, an appropriation of surplus net profits to guard against this contingency. Some companies have a definite policy predicated upon estimated savings to be made by a new piece of equipment as compared with the old, of amortizing the cost of the equipment within a definite period out of the earnings. This again presupposes that the price level and the production are such, or will remain so, as to permit the estimated earnings and the amortization of the investment in the asset within the period contemplated.

It is estimated from the U. S. Treasury Department reports that there is invested in fixed assets in manufacturing industries in the United States, subject to depreciation, \$16,000,000,000.

Excessive depreciation charges may so increase the cost of sales as to lose business on a competitive basis; on the other hand, the manufacturer who fails to adequately provide for depreciation and ignores it in his costs is likely to secure business on a competitive basis but at the expense of the impairment of his stockholders' investment.

The Illinois Manufacturers' Costs Association states:

At the present time the most disputed question regarding the depreciation charge is whether or not the purpose in providing for depreciation is to distribute the cost of the fixed assets (less salvage value) over their estimated useful and productive life, or to provide out of the earnings made during their

estimated useful and productive life, capital to renew the depreciating assets on the basis of their replacement values, as these renewals become necessary.

Depreciation Should Be Cared for by Suitable Appropriations of Surplus or by Insurance. The author believes that it is sound practice to so apportion the depreciation charge as to recover through the current operating accounts the original investment in the asset, as and when the asset is replaced, and that it is more or less immaterial how this charge is determined, *i.e.*, straight line, reducing balance, sinking fund, or other method, provided that it represents the facts as nearly as possible and provided furthermore that fluctuations in value and the factor of obsolescence are cared for by suitable appropriations of surplus or by some form of insurance.

This means, then, that the variation in value at the time of replacement as compared with the original cost, due to the variation in the purchasing power of the dollar, as determined by valuation, would be cared for by an appropriation of surplus, specifically created for that purpose. During the period of high prices this appropriation would be larger, and, conversely, it would be lower during the low-price period of the business cycle.

CHAPTER IX

INSURANCE AS A MANAGEMENT PROBLEM

INSURANCE INDEX

An Outline Prepared by P. D. BETTERLEY, *Assistant Treasurer, Graton & Knight Company*, and a Committee of The American Management Association Consisting of W. W. CRAWFORD, *Assistant Treasurer, American Optical Company*; A. M. MACINTIRE, *Assistant Treasurer, United Fruit Company*

A summary of the essential features of business insurance, avoiding technical and legal details which require concentrated study. Many amplifications of coverage and methods are possible to suit the needs of individual risks.

Basic Principles of All Insurance.

- A. Need and responsibility for protection.
 1. Guarantee against uncertainties.
 2. Duty of management to guard against loss.
 3. When and how much to insure merits deliberate conclusion.
 4. Responsibility extends beyond purchase of ordinary insurance.
 5. Penalty results from ignorance of insurance requirements.
 6. Careful supervision and research pays.
 7. Affiliate only with the best insurance organizations.
- B. Fundamentals of good contracts.
 1. The written interpretation of a two-party agreement.
 2. Real value of a policy is its net worth.
 3. The intent should be understood by the contracting parties.
 4. Concurrent insurance may avoid controversy.
 5. The "standard form" may be modified to fit buyer's need.
 6. Binding contracts should be in force on time.
- C. Cooperative procedure.
 1. In principle insurance is mutual between buyer and seller.
 2. Policy is a contract of indemnity not a wager.
 3. Cooperative dealings increase protection and reduce costs.
 4. Discrimination in buying is security itself.

Media of Indemnity.

- A. Types of insurance organizations.
 1. Stock companies with reasonable guarantee of stable cost.

2. Mutual companies with contingent cost liability.
 3. Reciprocal, or exchanges, with wide division of responsibility
 4. Lloyds underwriters.
 5. Foreign companies.
 6. State funds.
 7. Self-insurance.
- B. Types of policies.**
1. Specific insurance.
 - a. Valued form and flat amount policies.
 - b. Excess cover can serve useful purpose.
 - c. Contingent form for unusual hazards.
 2. Blanket form.
 3. Floater type or general cover.
 4. All risk combinations.
 5. Coinsurance contract.
 6. Guaranteed amount form.
 7. Automatic insurance.

Contract Provisions.

- A. Obligations of contracting parties.**
1. Indemnity denied.
 - a. When there is an erroneous statement of conditions.
 - b. Because of material changes in circumstances.
 - c. If loss is due to abnormal events as during riots or war.
 - d. Agency misrepresentation, may avoid protection.
 2. Restricted rights of the insured.
 - a. Amount of insurance limited to actual values.
 - b. Property cannot be moved at will.
 - c. Protection is not automatically transferred by sale.
 - d. Cancellation with penalties.
 3. Rights of the insurers at time of loss.
 - a. Prompt notification, inspection, and reduction of damage.
 - b. Privilege of replacing property, and recovery.
 - c. Legitimate cause and effect must be evident.
 - d. Indemnity according to contract terms.
- B. Third-party interests.**
1. Mortgagees have prior claim in settlement.
 2. General public benefits by complete protection.
 3. Employees need security for their disability claims.
- C. Special policy conditions.**
1. Period of effectiveness.
 2. Description of risk should be complete.
 3. Permits add breadth to coverage.
 4. Warranties are safeguards for the insured.
 5. Waiver to recovery from third parties to be acknowledged.
 6. Falling building clause is not conducive to good protection.
 7. Reinstatement is essential when property is restored.

Regulating Factors.

- A. Costs of insurance and standard rates are affected by:
 - 1. Nature of risk and location.
 - 2. Facilities for prevention.
 - 3. Maintenance and care.
 - 4. Type of inspections.
 - 5. Structural changes.
 - 6. Segregation of property.
 - 7. Exposure hazards.
 - 8. Frequency of losses.
 - 9. Form of protection.
 - 10. Term written for.
- B. Valuations.
 - 1. Consider all insurable values whether or not on record.
 - 2. Replacement consistent with practical use is logical.
 - 3. Underground structures may be damaged.
 - 4. Include property of others if liability therefor exists.
 - 5. Effect of coinsurance clause should be realized.
 - 6. Settlement basis should be predetermined.

The Ultimate Test.

- A. When loss occurs.
 - 1. Act as though not insured.
 - 2. Notify owners and insurers immediately.
 - 3. Insurance manager should be on location.
 - 4. Immediate salvage efforts are essential.
 - 5. Avert further loss by preserving usable property.
- B. Settlement of loss.
 - 1. A complete claim, deliberately made, inspires confidence.
 - 2. Reasonable proof of loss is required.
 - 3. Disagreement impairs collection and future relationship.
 - 4. Arbitration and court proceedings are costly.
 - 5. Abandonment to insurers is not permitted.
 - 6. Subrogation and prosecution may be detrimental.
 - 7. Distribution is proportionate to obligation assumed.
 - 8. Each insurer pays its legal share only.
 - 9. Insolvency of insurer leaves no recourse to claimant.

INSURABLE RISKS**Property Hazards.**

- A. Fire and related losses.
 - 1. Incidental losses by natural elements or theft.
 - 2. Inherent explosion.
 - 3. Replacement affected by ordinance.
 - 4. Smoke, smudge, and water.
 - 5. Underground piping, structures, and foundations.

- B. Leakage.*
 - 1. Chemicals and gases.
 - 2. Rain water and snow.
 - 3. Service water and steam.
 - 4. Sprinkler systems.
- C. Natural elements.*
 - 1. Earthquake.
 - 2. Flood, rain, and tidal wave.
 - 3. Hail.
 - 4. Lightning.
 - 5. Windstorm, tornado, cyclone.
- D. Breakage and collapse.*
 - 1. Aircraft.
 - 2. Electrical equipment.
 - 3. Engine breakdown, including turbines and flywheels.
 - 4. Explosion of boilers and pressure tanks.
 - a. Direct damage.*
 - b. Extra costs for repairs.*
 - c. Distributing pipes.*
 - d. Fractures.*
 - 5. Machinery and equipment.
 - 6. Plate glass.
 - 7. Special hazards of the industry.
- E. Criminal.*
 - 1. Burglary.
 - 2. Embezzlement and misappropriation.
 - 3. Forgery.
 - 4. Messenger holdup.
 - 5. Pay-roll robbery.
 - 6. Theft, larceny, and pilferage.
- F. Surety.*
 - 1. Bid bonds (annual and specific).
 - 2. Guarantee of promises.
 - 3. Lost instrument bonds.
 - 4. Mutual insurance assessment bonds.
 - 5. Performance of contract.
- G. Transportation.*
 - 1. Automotive and aircraft.
 - a. Transport risk.*
 - b. Hail, lightning, windstorm, floods.*
 - c. Collision.*
 - d. Theft and pilferage.*
 - 2. Baggage and tourist floater.
 - 3. Marine, foreign, and domestic.
 - a. All-risk policy form.*
 - b. Blanket policy form.*
 - c. Open policy form.*
 - d. Specific policy form.*

4. Railroad transit, express, parcel post, and registered mail.
- H. Miscellaneous.
 1. Aircraft damage.
 2. Credit insurance.
 3. Demolition of buildings.
 4. Errors and omissions insurance.
 5. Fine arts all-risk cover.
 6. Improvements and betterments.
 7. Livestock.
 8. Mortgage loans.
 9. Patent infringement.
 10. Personal effects "all risks" insurance.
 11. Strike, riot, civil commotion, and war.
 12. Title and land values.

Liability Insurance (Personal Injury, Damage, and Property Loss).

- A. Contractor's liability.
 1. Due to operations.
 2. Defective conditions.
- B. Employers' liability and workmen's compensation.
- C. Explosion.
 1. Boilers and pressure tanks.
 2. Engines, flywheels, and machinery.
 3. Industrial.
- D. Infringement of patents.
- E. Landlord's, owner's, and tenant's direct or contingent liability.
- F. Mechanics' liability.
- G. Motor vehicles, etc.
 1. Aircraft.
 2. Automobile direct and contingent liability.
 3. Teams.
- H. Public.
 1. Aircraft.
 2. Athletic events.
 3. Bailee's customers risk (laundries, warehouses, etc.).
 4. Carrier's liability.
 5. Catastrophe hazard.
 6. Contractors' and public service companies operations.
 7. Defective products, machines, and equipment.
 8. Elevator, crane, and track operations.
 9. General.
 10. Malpractice and professional risk.
 11. Owner's and contractor's protective.
 12. Trustee's, bankers', and agents' liability.
 - a. Blanket bond covering fraud and shortage.
 - b. Forgery and alteration.
 - c. Theft.

Earning Power.

- A. Accident and health insurance.**
 - 1. Employee groups.
 - 2. Individuals.
 - 3. Field representatives.
- B. Life insurance.**
 - 1. For executives.
 - a. New factor of value to insure.
 - b. Basis for valuation.
 - c. Means of credit stabilization.
 - 2. Group coverage for employees.
 - a. Mortgage protection.
 - b. Contributory plan for protection and thrift.
 - c. As a welfare measure.
- C. Pensions or insured retirement plans.**
 - 1. Importance of, to employer and employee.
 - 2. Possible benefits.
 - 3. Contractual features.
 - 4. Contributory plan.
 - 5. Annuity payments.
 - 6. Withdrawals.
 - 7. Division of costs.
- D. Profits anticipated.**
 - 1. Contract violation.
 - 2. Faithful performance.
 - 3. Investment guarantee.
 - 4. Patent infringements.
 - 5. Production.
 - 6. Sales.
- E. Rentals and leases.**
 - 1. Owners' rented property losses.
 - 2. Lessees' losses from casualties.
- F. Use and occupancy (business interruption insurance).**
 - 1. Fire.
 - 2. Sprinkler system.
 - 3. Natural elements.
 - a. Earthquake.
 - b. Lightning.
 - c. Water, rain, and tidal waves.
 - d. Windstorm, tornado, cyclone.
 - 4. Power units.
 - a. Loss due to breakdown.
 - b. Failure of public service.
 - 5. Electrical.
 - 6. Special machinery.
 - 7. Service interruption.
 - 8. Strikes, riots, war, etc.

INSURANCE WITH SECURITY

By P. D. BETTERLEY, *Assistant Treasurer, Graton & Knight Company*

One of the greatest enterprises today is insurance, and that portion which pertains to property, liability, and casualty risks is a tremendous factor in business management, while life and accident insurance occupy an increasingly prominent position. Insurance is a method of distributing infrequent but serious losses among many; to indemnify unfortunate persons having interest in things of material value. Scarcely a dollar of assets is free from insurable risk.

The buyer of insurance should realize that he pays for losses; that rates are largely regulated by experience. The results will be less restrictive laws and large economic savings. Business management spends large sums for research; to check losses in various lines; to guard property against mechanical damage, wear and tear; yet fails to control hazards and often neglects insurance. Deliberate calculation rather than fear or actual catastrophe should determine when and how much to insure.

There should not be any mystery about insurance. It may be complicated, but it is understandable, and nothing should be taken for granted. Frequently changes in risks are known only to the insured, therefore he must assume responsibility for the security of his protection.

When an insurable loss occurs and indemnities are less than is required to restore the value, there is an irreparable loss, but most of these can be avoided by diligent application to the subject of insurance protection at all times.

Basic Principles of All Insurance. *Need of Insurance.* It is to guarantee as far as possible against uncertainties: to maintain financial security and credit. It is certainly the duty of management to guard against losses in business, to have on hand as promptly as possible, working capital to replace destroyed property or source of earnings.

Collateral Interests. The public is interested through their investments in business enterprises, including deposits in banks. The latter loan their funds only on ample security, usually in the form of liens on property. If these properties are not so protected by insurance that their replacement can be guaranteed in case of destruction, then the resources of the bank and depositors may be diminished.

Method of Protection. It is not always necessary to insure the risk with a company or association designed for the purpose, but the security is greater when insurance is so placed. If the probable losses are greater for a reasonable time than the cost of insurance, then there can be no argument as to the desirability of purchasing the protection. In a general way it may be safe to follow the rule that if the risk is distributed among many units, so that the maximum loss in any one unit is limited to a small proportion of the aggregate, it is possible to fund the risk instead of purchasing insurance. Much depends upon the number of units, values involved, the rates of insurance, and possible control of the hazards.

Responsibility of Management. Responsibility does not cease with the purchase of types of insurance in common use. No insurance company can fully anticipate the needs of a risk as distinguished from another risk. Certain fundamentals will govern in each case, but there is usually need of modifications to fit particular conditions, and the manager is in a position to analyze these requirements better than an outsider. It is the duty of the buyer to procure such insurance as a careful, prudent person would obtain, to secure the property and assets. His failure to do this, to exercise foresight, will result in permanent reduction of net worth.

Supervision and Research. There is need of preserving proper records, making frequent study of changing conditions, following decisions of the insurance companies and the courts. Intelligent research tends to create measures for prevention.

It is quite evident that insurance security involves consideration of legal rights, contractual obligations, values, operations, future developments, liability as owner, operator, or employer.

All of the foregoing requirements would seem to warrant placing in charge of insurance one who has experience, judgment, initiative, vision, and thoroughness as special qualifications. Since it involves the preservation and security of values, the treasurer, or someone in that line of activity is the logical one to assume responsibility, aided in major problems by a committee.

Additional security may be effected by contacts with well informed insurance officials, agents, or advisers. Exchange of experience with other buyers in non-competitive lines is mutually helpful.

Stable Connections. Having first made contact with reliable underwriters, whose reputation has been established for fair treatment and who are licensed to do business in your state, continue the connection, because the insurer who has enjoyed your business for a long period of time is bound to give you the benefit of a doubt in time of misfortune. If insured with stock companies the same reasoning holds true with regard to the local agency connection. Work with them, not without them.

Fundamentals of Good Contracts. *Real Value of an Insurance Policy Is Its Net Worth.* The intent of the contract should be understood. It is a promise to pay for loss sustained under the peril insured against, but it does not cover indirect or all incidental losses. There should be an interpretation of its various clauses, for mutual agreement is the foundation of a policy.

Concurrent Insurance. All policies covering one single risk should be written exactly alike, in order that there may be no question as to contribution by the various insurers. Hazards of a similar character, such as liability to the public and employees, should be covered by policies which allow no gaps in protection. Much delay and embarrassment can be avoided at time of loss settlement by complete agreement beforehand.

Policy Standards. It is a well-established rule that if an uncertainty exists, the one causing that condition must bear the penalty, therefore be sure that the insurance policy is what you think it is. There is a standard form which must be the basis of the insurance contract, but it may be qualified to fit buyers' needs. The written portion of a policy supersedes the printed portion, and the last endorsement governs in preference to earlier ones.

It is the duty of the insured to inform himself of the terms, considered in relation to every possible loss, ascertaining if every agreement made with the insurance companies will stand the test.

Need of Anticipation. Buyers of insurance would do well to know that the insurance policy has actually been issued at the time that they desire to have the risk covered. If time does not permit of this a binder can usually be obtained, and if negotiated by authorized persons, it may be perfectly safe, but whenever possible insurance needs should be anticipated. Legally a contract of insurance is not binding until the insurer is satisfied, has accepted the risk, and received the deposit premium.

Authority of Agents. A notice given to a broker or agent may be accepted by the insurance companies but is not always binding. Ordinarily the broker is the agent of the insured, empowered only to accept premiums, but every representative is governed by his contract with the underwriter.

The rights of agents to waive requirements or change policy conditions are very limited, and there is great difference between soliciting agents, collectors, and representatives empowered to act. Neglect of these features has caused many irrecoverable losses.

Completing the Contract. It is common practice to negotiate for insurance, remitting for the premium in a reasonable time, and this procedure is safe under ordinary conditions, although the insurance company has the legal right to cancel for non-payment, as stated in most contracts. If the policy is to be held by a bank or other mortgagees, the property owner should examine them and obtain a duplicate or insurance certificate, certifying to the existence of the policy. It is also important that all policies, their riders and endorsements, be signed by the company or its authorized agents. All endorsements should be firmly attached to the original contract for they are a part of it.

Cooperative Procedure. Contract Observance. All insurance is mutual in principle, the loss being met through contributions by members of the insured group. The insurance contract is personal in character, and its value depends upon the observance of good faith, throughout its effective period. It is not a wager, guaranteeing to pay a specified sum in case of misfortune, but is an agreement of indemnity to compensate within the scope of the policy.

Value of Cooperation. The insurer will select and rate risks on a loss cost basis, therefore the integrity and cooperative spirit of the insured are essential factors in determining the cost and protection of insurance. Voluntary efforts to reduce the hazards should be reflected in lower premium costs, and more liberal claim adjustments.

Security Demands Only the Best. There are regulations set up to protect the insurance organization as well as the public against fraud and discrimination, but it may be possible to modify the ordinary insurance contract. Adequate knowledge of the risk and insurance principles will enable the buyer to obtain the type of protection which will carry with it security.

Media of Indemnity. Stock Companies. This group issues non-participating policies with reasonable assurance of stable costs, but a material change in hazards, or experience, may affect the aggregate premium. They operate through agents and brokers, the former being direct representatives, whereas

the latter may indirectly sell insurance for a number of companies. There are advantages in having direct representatives of the company near at hand, and competent agents may furnish valuable assistance.

Through association of many companies they maintain extensive laboratories for the study of hazards and testing of protective devices. In some communities they support protective agencies, who assist at time of a fire in keeping down the loss by salvage work. They will insure practically any risk, the rates varying according to the hazard.

Mutual Companies. The second principal source of supply is the mutual companies, the insured being the stockholder and participating in any profits accruing from the business. This method results in a lower cost under average experience, but carries with it a contingent assessment liability, continuing for some time after expiration of the policy and varying in amount. In some instances non-assessable policies with dividend features are written, also contracts with discounted initial rates and supplemental dividends. Under good management these mutuals have no occasion to call upon the assured for additional funds; in fact most of them pay liberal dividends.

There are many groups, some of them specializing in a particular line, such as the grain and hardware mutuals. Others will insure diversified factory lines which measure up to certain standards. Some of these companies include sprinkler leakage, windstorm, hail and inherent explosive hazards along with their fire protection. The Factory Mutual group also maintains valuable testing laboratories and an appraisal department, which furnishes a good valuation of their insured properties in considerable detail, without any charge. Mutuals write workmen's compensation extensively and certain other risks.

Reciprocal and Interinsurance Groups. There are reciprocal organizations and exchanges which operate on a different basis from other insurers. A group of subscribers agree to insure each other by pooling their interests, and the affairs are looked after by an agent or attorney, with power to act. There is no corporate existence. In case of a loss sustained by one of their members all of the others contribute in proportion that their insurance bears to the aggregate, but the one sustaining the loss does not contribute toward his own benefits. A condition of this insurance is the assumption of liability by the insured up to as high as ten years' premium.

The responsibility and success of the plan depends upon the "attorney in fact," who has practically everything in his control. A large amount of insurance is written by these groups, even in states where they have been denied license to sell through representatives.

Lloyd's Underwriters. Lloyd's insurance groups follow a method of insurance by which a large number of individual underwriters agree to assume a proportion of losses occurring under a single policy, and the security is limited to the financial ability of each underwriter. This type is more generally used abroad than in this country.

Foreign Agencies. Foreign insurance companies maintain departments in the United States which they operate with good financial security and in much the same manner as domestic companies, being under the jurisdiction of our insurance laws.

In the case of risks located abroad or marine imports, it is recommended that the risk be covered either by domestic companies, or those foreign companies who maintain strictly independent subsidiaries in this country. Great distance does not develop the same cooperative understanding that may be expected when dealing with domestic organizations. When necessary to collect under court action, the claimant is at great disadvantage.

State or governmental funds operated by government departments with the intent of furnishing insurance at cost, on workmen's compensation risks principally. Risks outside of a state cannot be protected by the local state fund and this creates some embarrassment for the concern that does an interstate business.

In some jurisdictions insurance in state funds is compulsory. Such methods are not consistent with sound business practices and any tendency of government agencies to enter the business insurance field should be discouraged.

Self-insurance. The operator or owner assumes his own risk, creating an unencumbered reserve or guarantee, sufficient to provide direct compensation for losses. Without such provision no insurance can be said to exist. Self-insurance lacks the security which goes with outside insurance, and the success of this method depends upon the direct interest of the management.

It is possible to handle multiple units of risk in this way under favorable conditions; for instance a large number of small stores might be thus handled with considerable saving, whereas concentrated property would involve too much risk. A large number of employees in an individual factory might be compensated for accidents without particular hazard because there are many units of risk.

This method directly focuses the attention of the management on losses and often brings about preventative measures which would be otherwise ignored. It is possible and often advisable to buy insurance to cover above certain limits of loss, on self-insured risks.

Other examples of self-insurance practice are personal guarantees, trust funds, and private insurance organizations.

Types of Policies. *Specific insurance*, covering a particular class of property against one type of hazard, such as fire insurance on a building, but not including the contents. It is practical where there is no likelihood of change in the risk, and when values are fairly stable.

When merchandise is subject to nominal damage, such as raw stock in green, or wet process, a "flat amount contract" written for such arbitrary amount as the estimated maximum loss will save expense as compared with other forms. It accomplishes the same result on vacant property pending disposal, where there is a small market value but large replacement cost. It is applicable on property which has served its original purpose, if replacement is to be on a smaller scale.

A "valued form" is used in protecting paintings, scientific instruments, special machinery, etc., which do not have any established market value. There must be complete agreement as to values before insurance is affected. Marine or transit values are declared in advance.

Another variation of the valued form occasionally used is the three-fourths value contract, the insured agreeing to accept in settlement no more than three fourths of the value of the property at the time of loss. Partial losses will be paid in full. If the liability of the insurers is less for total loss than the amount of insurance, the premium on the excess will be refunded for the full time of the policy.

Policies are also issued with a three-fourths loss clause under which the insurer agrees to pay only three fourths the amount of any loss up to the limit of the policy.

Excess cover insurance may be used in connection with specific insurance, but does not normally pay any portion of the loss which was assumed by the specific policy. It may serve as reinsurance under a self-insured plan, taking care of all losses above the maximum amount which the self-insurance plan assumes. There may exist a contingent liability in respect to a specific hazard, such as the operation of automobiles by representatives, and protection for this type of risk is now available.

Blanket insurance, a very desirable type of policy which covers one type of risk on more than one class of property, such as buildings and contents or public warehouse risks. It will cover the contents if moved from a building to an adjacent one on the premises of the same insured. Heavy losses have been sustained where insurance covered contents in each building for a specific amount, the aggregate insurance being sufficient, but the values being shifted so that there was a shortage of protection in one building. It is also good coverage for automobile fleets, fidelity bonds, and similar groups of units subject to the same risk. There is much less occasion for disputed claims under the blanket form.

A combination policy is used in covering more than one type of risk, such as fire, lightning, sprinkler leakage, and windstorm. Another example is the open marine policy, covering many navigation risks. A single policy may also cover a risk in which the parent company and subsidiaries have an insurable interest.

Another variation of blanket protection is the all risks policy, suitable for products in circulation, equity in deferred payment sales, salesmen's samples and similar distributed risks.

Coinurance Contract. While more often referred to as a clause in the policy, it merits a definite form classification because of its far-reaching effect. The owner agrees to insure at least 80 per cent or other stipulated percentage of value. This feature is designed to equalize rates and losses by the placement of a fair amount of insurance, and in the event of failure to do so, the insured must assume a portion of the loss. It is an equitable method but quite generally misunderstood as to its effect upon settlements in the event of partial loss. It operates as follows:

1. If the amount of insurance equals the percentage of value called for, at the time of loss, any complete or partial loss will be paid in full—not exceeding limits of the policies applying.

2. If the amount of insurance is less than required as above, the settlement will be for such proportion of any loss as the amount insured bears to the amount required to be placed.

There is considerable danger of being coinsurers when there are large values belonging to others for which the insured is responsible; in fact, separate specific insurance is sometimes required by the owner to guard against such shortage of protection.

Guaranteed Amount Form. This is especially good when there are fluctuating values due to change in inventory volume and market prices, or where a material portion of the property is subject to nominal damage only.

A resulting benefit is the avoidance of maximum insurance to cover the peak values and subsequent short-rate cancellation penalties. A statement of values must be filed yearly and unless insurance carried is equal to 100 per cent of stated value the insured stands a proportionate part of the loss.

General Cover. This form is used to cover products which in the course of manufacture or assembly may be shifted from one locality to another, a limit being fixed for each location equal to 100 per cent of value. Provision is usually made for reporting the values at each location, and the rates are based on the conditions at each place.

Floater policy, for merchandise variously located in branch warehouses, stores, and on consignment with dealers. It operates either as an excess or full cover policy. It is written for the total estimated value, setting a limit of protection for each location which is ample to cover values at any time. Reports of actual values may be rendered periodically to the insurers, and an adjustment of premium made at the end of the policy term. It is sometimes written with a coinsurance clause. It has these advantages among others:

1. It obviates constant check on the insurable values.
2. It reduces the aggregate amount of insurance to be carried because the protection "floats."
3. It may cover merchandise sent to another establishment for processing.
4. Eliminates possibility of loss due to failure of dealers to place sufficient insurance.
5. Avoids loss due to insolvency of consignees or their insurers.
6. It covers owner's interest in property sold under special conditions.
7. It protects merchandise stored in transportation companies' warehouses after responsibility of the latter ceases.
8. It may cover exhibits.

Automatic Insurance. This is not a title of any particular form of insurance contract which is now available, but represents a method of insuring. There are so many changes in the nature, value, and volume of risks, that it is quite necessary for the security of insurance to have it apply automatically. It is next to impossible to anticipate maximum requirements at minimum cost in time to adequately protect all risks. The following list includes types of automatic contracts and examples of risks they may cover:

1. Blanket form, buildings and contents in a contiguous group against single risk of fire, wind storm, use and occupancy, etc.
2. Floater, covering merchandise in various locations against risks of fire, windstorm, and allied lines.
3. Open marine policy, covering all merchandise shipped, against various transportation hazards, from shipping point to final destination.

4. Transit policy for railroad, express, automobile, aircraft, and similar transportation hazards.
5. Open parcel post policies. Bailees' customers property risk.
6. All risk policies for such items as deferred payment sales and products in circulation.
7. Contractors' and mechanics' liability covering operations in various states.
8. Excess policy to cover higher limits of property loss, or liability, otherwise specifically insured.
9. Contingent liability contract, separately insuring against various possible claims.
10. Automobile fleet policy, against usual insurable risks.
11. Fidelity bonds, a position form to cover various persons in specified positions, or a blanket contract covering all employees.
12. Group life, accident, health, and retirement plans.

Obligations of Contracting Parties. *Erroneous Statements May Bar Recovery.* The statement of conditions must be substantially correct, and the fact that the insurer might readily discover an error is no relief to the insured. The insurer does not contemplate protection for unusual risks unless there has been a voluntary disclosure of material facts and evidence of insurable interest.

Change in Circumstances May Void Policy. If there are changes which greatly increase the hazard or place the risk in a different class, the written consent of the insuring companies should be secured in advance and become a part of the policy contract. Some common causes are the use of dangerous materials, ceasing operations, vacancy, assignments, and alterations.

Loss Must Be Direct Result of Risk Insured against. Insurance does not attempt to protect men against all consequences of accidents, and ordinary insurance policies do not cover in case of strikes, riots, war, earthquakes, or similar abnormal conditions. The common use of explosive materials in industry has created many disputes as to whether a loss was occasioned by fire or explosion. Under various surety and liability risks a claim must be substantiated by reasonably conclusive evidence.

Disagreement between Insurer and Agent May Affect Collection. The contract between agents and insuring companies may be the indirect cause of an uncollectable claim, the insurers declining to back up the representations of the agent if the acts of the latter are contrary to the agency agreement. The buyer has no way of knowing what arrangements have been made, therefore he should be very cautious in respect to any deviations from established practice, being sure that the underwriting organization accepts the conditions before the insurance contract becomes effective.

Restricted Rights of Insureds. Study the contract limitations, for many acts common in business procedure may invalidate the protection. Insurance in excess of indemnity values is not permitted.

It is not permissible to move insured property to an entirely different location without the consent of the insurer, either at time of removal or by prior understanding, for the hazards may be much greater in the new location. The value of a blanket or floater policy is fully realized under changeable conditions of this character, also avoiding excess insurance or cancellation penalties.

Change of Ownership Stops Protection. The buyer of property should not overlook the fact that insurance protection is not automatically transferred at the time of sale, for the insurable interest has changed hands and a new contract must be negotiated. Even a change in name must be recorded and a lien upon property, without consent of the insurer, may void the policy.

Rights of Insurer at Time of Loss. They are entitled to immediate notification and to enter insured's premises for inspection in the interests of all parties. They also have the privilege of a reasonable time in which to make settlement.

When physical property is involved, they have the option of paying equivalent value in cash or replacing with property of similar kind and quality.

When a third party may be considered liable for the loss, the insurers may exercise the right under the subrogation clause of attempting recovery from the said third party.

Indemnity Paid Only When Terms Are Complied with. Occasionally policies are written which guarantee to the holder payment of the amount specified on the face of the policy, but usually the settlement is based on the actual loss sustained, or such proportion thereof as the insurer has agreed to pay under the coinsurance clause, and other provisions of the contract. Legitimate cause and effect must be evident.

Third-party Interests. Mortgagees. They have a right to expect that their interests will be taken care of, their loss payable direct to them, and may call for filing of the policies. Advance notice of cancellation is required. They should ascertain that the insurance is in proper form for in the case of loss of the collateral, the indemnity received under policies becomes the real collateral for the loan. If there is a short settlement of a loss, the mortgagees are paid first and not proportionately with the insured.

If subsidiary companies or other parties are interested in the risk, they should be named in the policy, whether their concern be through the medium of ownership, or liability for any casualty.

Public Welfare. The general public has considerable interest in the protection of risks. Carelessness and widespread destruction seriously affect the aggregate valuation of taxable properties, and cause removal of business from a community. Semipublic organizations and public officials can do a great deal by cooperative efforts in the prevention of waste and furtherance of sound principles of insurance.

Under compensation or liability policies, employees and the general public should receive consideration as to the security of their possible claims.

Special Policy Conditions. Term Written for. The period covered by the policy is definite—to the minute—and protection should be continuous without any lapse of time. There have been cases of disputed liability because of the fact that loss occurred at about the hour when the insurance expired, with damage continuing after the actual time limit had been reached. If there is continued and unbroken protection, the claim for aggregate loss may be successfully maintained.

Description of Subjects at Risk. It is wise to name most of them so as to establish the intent of the contract. Supplementing this there should be a general classification covering items "not otherwise provided for." Proper-

ties sometimes overlooked are those located in railroad cars, in yards, articles held in trust, records and patterns.

Necessity of Permits. If there are stipulations in the standard policy which are contrary to the actual conditions or wishes of the insured, they are nevertheless fully effective until modifying permits become a part of the contract. This may appear to be a curtailment of liberties in owner's use of his property, but it is necessary to have general safeguards for the protection of all buyers of insurance.

Warranties Must Be Faithfully Observed. The insured undertakes to maintain standards of protection and avoid unnecessary risk. If a breach of these warranties exists at time of loss the insurance may become invalid. The mere fact that representatives of the insuring organization do not discover the violation does not relieve the insured of responsibility.

Waiver of Rights. When railroads have side tracks on the premises of the insured, it is customary for them to require a waiver of right to recover for losses due to their operations there. As this limits recovery by the insuring companies, it is essential that the policy contain an acknowledgment of this condition or similar ones.

Fallen Building Clause. It stipulates that fire insurance ceases if a building, or part of it, falls. While the building may be seriously impaired by collapse, there is yet some value remaining to be protected. The absence of this clause materially adds to the security in case of earthquake or tornado damage, and where explosion may be a contributory cause of the loss.

Reinstatement after Loss. Many property loss policies are reduced or cease to cover after loss and the amount must be reinstated with proportionate premium charge. There are some exceptions, such as marine policies and those which contain an automatic reinstatement clause. There are few limitations under liability policies, the contract covering as many casualties as may occur.

Cost-regulating Factors. Nature of Risk Affects Costs of Insurance. Standard rates are made for certain classes of risks, adjusted to fit the conditions existing under any one particular policy. It does make a great deal of difference where the insured is located, effective water supply, the type of construction, and the nature of operations. The moral risk is seriously affected by the presence of undesirable tenants in the same or adjoining building.

Preventive Measures Reduce Premiums. To indicate the value of an automatic sprinkler system, the amount saved in insurance premiums will in many cases pay for the entire installation in five to ten years. The division of a risk into multiple units by complete fire walls materially reduces the hazard.

Watchmen should be selected by the judgment that they will exercise in emergency—these positions should not be filled by superannuated employees. A few unqualified men should not be given complete control of large property values which, during working hours, are protected by almost the entire organization.

These general principles of prevention apply equally well to many risks other than fire.

Maintenance and Care. These are big factors in keeping down the cost of insurance. Casualties do not occur at stated time or place, therefore it is wise to avoid spasms of carefulness, cleanliness and prevention. It is far better to safeguard risks so that small casualties cannot grow to become large ones.

Inspections. They should not be treated as a nuisance by either management or employees, but rather as a united effort to keep down losses from which all suffer. There should be cooperation between the manager, owner, and the insurers' inspection department, but an inspection service within the organization should be constantly maintained and effectively keep conditions up to standard.

The insurance manager will find familiarity with the physical conditions of the risk a great aid in securing full protection at minimum cost. He should know of changes which are contemplated in building construction, alterations, installation of machinery, relocation of property, changes in operations, and use of hazardous materials.

Segregation and Control of Hazards. Insurable values should be well distributed and management can so regulate its risks as to minimize both the insurance costs and losses. If there is needless exposure to a hazard, it is obvious what the result will be on insurance rates. The insuring organizations are also guided by the frequency of losses, even though the amount of actual damage is small. Small losses should be investigated and potential risks considered, for escape from a serious loss may be due to fortunate circumstances.

Form of Insurance Affects Costs. Suitable coverage is available which avoids overinsurance (see types of contracts). Frequent cancellations of policies add materially to the cost through short rate penalties, and consolidation of policies of the same kind decreases labor and error. Good risks with stable values may be covered for three years at a lower rate than for one year.

Valuations. Importance of Authentic Values. These are a source of concern to the manager of insurance because of their relation to the amount of insurance to be placed, as well as the basis for determining the amount of settlement. As many books of accounts carry property at cost or market, whichever is lower, it is obviously unsafe to rely solely upon those figures. Neither can the current market value be used as the prices fluctuate and represent diversified interests scattered over a wide area, which would tend to average rather than actual values at a given location. An appraisal is a reliable basis if the record is kept up to date.

It is frequently necessary to use all of the foregoing sources of information, and the fact that the insured valuation does not agree with any of these records does not prejudice the collection of indemnity. True insurable value is the cost of replacement at the time of loss with due allowance for obsolescence and practical use.

Excluded Property. Underground foundations, piping, and items of this character which are normally included in building cost records are excluded in appraisals of insurable values and in the average insurance policy. The susceptibility to damage is rather remote, but quite possible under certain conditions, therefore should be considered.

Market or Cash Value Clause. Security will be more complete if the basis for settlement is made clear before loss occurs. For example, it may be agreed that the value shall be based on a published price list, less current discounts.

A predetermined basic value clause is particularly good in long time, or multiple processes of manufacture. If there are intermediate processes, producing goods which may be sold, they should carry their proportionate share of fixed charges and overhead, consistent with the value of the finished merchandise.

An arbitrary value may be established to cover unusual cases.

Property of Others. The temporary possessor of property should protect it, providing there is a possibility that he may be held accountable to the legal owner. It is essential that such items be included in the insurable values, especially if there is a coinsurance clause in the contract.

Circulating Property. The legal owner should make sure that his property which is at another location for processing, use, or sale is adequately covered by insurance. It is better to keep it under the owner's policies and control, and a floater policy is an automatic device for such security of protection.

The Ultimate Test, Settlement of Loss. What to Do When Loss Occurs. Action should be governed by such judgment as would be exercised if there had been no insurance. Those in charge should do what is reasonable to prevent further loss by salvage operations and restore protection for that property remaining. The owner's representatives and insurers should be notified immediately, and effort made to reduce the damage by refinishing or preserving such property as may be usable.

Insurance Manager's Duties. He should be promptly at the location of the damage and cooperate with other constituted authorities. Knowing the actual circumstances pertaining to a loss, he will be better prepared for subsequent negotiations, and there will be less likelihood of insurable losses being uncollectable. There is an exceedingly important connection between placing of insurance, salvage and restoration activities, and the settlement of loss.

Making Up the Claim. While a prompt settlement is to be desired in order to restore the activities of the business, there is danger in too hasty action before the effects of the casualty are fully realized. Look over everything so that nothing may be overlooked. If there is a coinsurance clause it may be to the claimant's advantage to place his losses at a conservative figure, for the application of maximum values may result in the insured contributing a greater proportion of the loss than he otherwise would.

Proof of Loss. When negotiating with adjusters it would be more tactful not to press too vigorously on disputed values even though the insured is convinced of the justice of his claim. Reserve decision until the list is completely gone over. The adjuster is not presumed to be as familiar with the property as the owner, and some portion of the claim may appear excessive to him, while other items may seem to be undervalued, the grand total meeting with the approval of both parties. There is much less likelihood of a controversy if the procedure is along the lines of common sense and cooperative spirit. There must be a reasonable proof of loss, and the burden of proof rests with the assured.

Dangers of Disagreement, Arbitration. It is better to compromise, for the cost and delay due to arbitration and court procedure materially reduces the amount realized from the claim. A good agency connection, or an established reputation with all insurers, helps to evade such undesirable experiences.

Either party may call in advisers, although undue influence and prejudice should be avoided. Adjusters should not call in advisers in a line competitive with that of the insured, without the consent of the latter.

Abandonment of Property. The owner of damaged property is not permitted to abandon it to the insurers, although the insurers have the privilege of taking such property as they pay a full loss for. It is sometimes customary, more particularly in marine losses, to dispose of the damaged goods at auction, but it might be wiser to accept a smaller indemnity than to risk sales reputation by such disposal of special merchandise. The manufacturer has facilities for reconditioning to advantage of himself and the insurers.

Subrogation and Prosecution. Under the subrogation clause the insurers may bring action direct or in name of the insured against those actually responsible for the loss, but before permitting such action the claimant should consider the probable effect on his business through such publicity or the possibility of counteraction. Such experience is not confined to fire insurance, but many insurable risks.

Distribution of Loss. The insurance manager often feels quite secure if he has policies, aggregating the maximum possible loss. Aside from the effect of coinsurance clauses, non-concurrency and failure to comply with the various contract regulations, the real test comes when a claim is made.

Each insuring company is obligated to pay only its legal share of the loss. The distribution is made proportionate, and the fact that one insurer denies liability does not impose any additional obligation upon those remaining. Whether or not such denial is due to insolvency, or invalidated coverage due to acts of the insured, the latter must stand such portion of the loss as the insurer refuses to pay.

Summary. The entire cost of protection must be borne by the users, and insurance is made up of contributions to a general fund from which the victim of a casualty is reimbursed, providing there has been procured by him insurance which securely protects him against those losses. Eternal vigilance as the price of safety was never better exemplified than in the purchase and application of insurance.

CHAPTER I

HISTORY AND FUNDAMENTALS OF PRODUCTION

By CHARLES H. HATCH, *Vice President, Miller, Franklin and Company, Inc.*

The marvelous achievements of modern American mass production have been so thoroughly advertised that the man in the street and too often the man in the factory think of *all* production in terms of mass production. Mass production does, of course, account for a very large part of all the goods we produce, but only a comparatively small number of plants are or should be on a mass production basis. To assume that those highly efficient methods are universally applicable to all products is a grave and very expensive mistake as we shall see later on in this chapter. It is also a common error to think of all factories as being large. In 1919 the average number of employees per factory was 31.4 and 94.4 per cent of all manufacturing plants employed 100 or less workers.

History of Production. In order to understand the fundamentals that underlie the correct choice of organization, policies, methods and equipment it is desirable to have at least a superficial knowledge of the history of production, for modern production has evolved from the various methods that have been used in the past. The value of subdivision and specialization of labor which is one of the essentials of mass production was discovered hundreds of years ago. It has been proved thoroughly and found good.

Since modern production is an evolution, and since the choice of correct methods depends to a great extent upon the underlying philosophy of production, let us briefly summarize the history of the various stages through which production has evolved.

For convenience historians have divided the history of production into four principal stages which they label the "domestic period," the "handicraft period," the "cottage period," and the "factory system period."

The *domestic period* was the crudest. It practically ceased to exist in anything approaching a pure form with the rise of barter and exchange.

Under the domestic system each family produced everything it used—food, shelter, clothing, weapons, means of transportation, farm implements, and so on, from the raw material in its natural state to what it was pleased to call the finished state. That obviously is a method confined to people only a little above savagery.

But during this period, we can assume that some families learned to produce certain items better than others. The Stone Hatchet family became skilled in the manufacture of weapons, but with this increase in skill they became poorer and poorer as hunters. Up the river a few miles the Hunter family had never been able to achieve even reasonable skill in making things with

their hands, but as pursuers and killers of animals they were highly successful. Naturally they had given much thought and effort to preserving the hides of their kill.

So the Hunters soon found themselves carrying an inventory of cured hides far larger than they could use for clothing and tents, while they were handicapped by lack of effective hunting implements.

The opposite condition existed in the Stone Hatchet family. This was soon rectified by barter, through which simple procedure the wants of both were met. The plan worked so well that the Stone Hatchets concentrated on making hunting equipment which they traded not only for hides but in due time for shoes, clothes made out of hides and for all of the other things which other families had specialized in producing.

Specialization having proved a valuable idea, production found itself in its second stage—the *handicraft period*. This transition took place largely during the Middle Ages.

Under the handicraft system each worker carried through the complete production of an article from the raw material to the finished product, but not usually from the rawest raw material. Thus a tanner transformed a raw hide into finished leather, the cobbler or the harness maker turned the finished hide into shoes or harness. But the cobbler, say, performed every operation essential to the making of the shoes, not as today when one man does nothing but make welts, another sews uppers and so on, each workman performing but a single simple operation.

It was during the handicraft period that the guild system grew up. Primarily a guild was a voluntary association of artisans in the same trade for mutual protection. They started practically as labor unions but before long the guilds partook of the nature of both unions and of what we know today as trade associations. They formulated strict rules as to the qualification of members and to govern the admittance and training of apprentices. They set standards of quality and, without doubt, did a good deal in the way of price fixing to insure that the workman would get a fair return for his effort and skill.

At times during the late Middle Ages the guilds exercised a large amount of power, not only in industry but in government as well. In some instances large numbers of workers in a guild grouped themselves into communities that not infrequently partook of the nature of factories. This was true to some extent of the European watchmakers and goldsmiths and diamond cutters.

In the handicraft period, it is to be remembered, there was no segregation of capital and labor. The craftsman was both, once his apprenticeship was completed. He owned the tools of his trade, he invested his own capital in raw materials and in the keep of his apprentices—which was about all the wages the poor apprentices got. He made the product himself and then went out and sold it, if he was not working on a definite order.

This system worked very well until the fifteenth or sixteenth century when exploration opened up trade routes to hitherto undreamed of markets for the products of the craftsmen. The possibilities of selling manufactured articles suddenly swept far beyond the ability of the craftsmen to produce.

As was to be expected by this time certain craftsmen had by industry and thrift laid up quite a little store of capital. They invested this in raw materials which they distributed to workers who lived largely in the country and who had before relied principally upon agriculture for a living. These *cottage dwellers* made up the raw materials into finished goods for the capitalist who collected the finished product and sold it either direct to the consumer or in bulk to merchants who distributed it to the far corners of the then rapidly expanding known world.

The workers generally owned their tools and had greater or less direct interest in the production of the goods, although none in their final distribution. As a matter of fact, it was during this so-called cottage period of production that the change over to the wage system took place.

While it is customary to think of the cottage period as one in which home work was the rule we actually find that along about the sixteenth century the cottage workers, instead of working at home, began in a small way to be grouped for convenience, and perhaps for the sake of better supervision, in what can by a stretch of the imagination be called "factories." In fact it appears that by the beginning of the nineteenth century there were in Germany some twenty of these factories, each sheltering from 100 to 500 workers. But these were not at all factories as we think of them today. Each worker owned his own tools, and although there were here and there some attempts to subdivide operations, the product was to an overwhelming extent still produced according to the tenets and methods of craftsmanship, each craftsman turning out a complete product.

It is frequently but erroneously held that the *beginning of the factory system* was coincident with the application of power to machinery. Actually, of course, the use of power, even of crude mechanical power, is about as old as history.

At first, men were used to turn wheels. Then animals were put to work in treadmills or to revolve a vertical shaft by means of a handle to which they were hitched. The use of water power and the power of the wind far antedates the discovery of the steam engine.

It is, as a matter of fact, probably pure coincidence which accounts for the fact that the steam engine came into use at about the time of the beginning of the factory system.

The best judgment of historians and industrialists is that the factory system of production was actually brought about by the invention, in the fifteen years from 1770 to 1785, of the spinning jenny, the water frame, the mule and the power loom—all inventions for the making of cloth which greatly increased the production possible per man hour.

It is to be noted that all of these devices could be operated by water power. In fact the spinning device referred to as the "water frame" was so called because it was intended to be operated by water power. Actually it was first run by horse power. Remember that the steam engine while it had been used to pump water from mines for many years had not yet been sufficiently perfected to enable its use for driving these new power-operated machines. Because it was then necessary to locate the machinery close to the waterfall

we naturally find that these new textile implements were grouped in what we can now recognize as factories.

The machines were so expensive, incidentally, that the average craftsman could not have bought one and so we find ownership of the tools passing from the workman to capitalists and the erstwhile craftsman hiring out to the capitalist for wages. It is also particularly to be noted that the new machines took from the worker the major part of his skill so that he became a mere machine tender.

With all its advantages over former sources of power, water power left much to be desired as it was necessary to place the factory where the water power existed, which was not always the most convenient place considering access to labor, supplies of raw materials, and convenience to markets.

But in 1785 the steam engine had been so perfected that it was finally possible to use it for driving the machinery in cotton mills. This great mobilization of power practically without limitation as to location was a tremendous stimulus to inventors who rapidly worked out methods by which many processes formerly done by hand could be done by means of power operated machinery.

The progress on those lines was rapid but not at all uniform in all industries. As a matter of fact improvements have been made all along during the nineteenth and twentieth centuries and right now are being made almost daily.

Beginnings of Mass Production. While we are prone to think of mass production as a very recent development for which our present generation deserves most of the credit the fact is that modified mass production existed in the first power operated cotton mill in the closing years of the eighteenth century. It did not take superhuman intelligence for those early manufacturers to discover that when a loom was set to make a certain construction of, say, sheeting, it was far more economical to continue it on that product indefinitely than to change it over to some other type of goods. And the very nature of the various machines used in the various steps of the process of converting raw cotton into finished cloth brought about the subdivision of labor which is an essential factor in mass production.

But this could not be done with certain types of goods for which the demand was narrower. So some looms had to operate turning out goods of one kind for a while and then shut down and adjustments made so that it could produce another type of cloth for a week or a month. This might be described as *job mass production*.

In certain other industries what was essentially mass production developed fairly soon after the invention of the steam engine. This was true of paper making, the rolling of steel, and the strictly processing industries such as reducing iron ore, flour milling, and some few others. But even with the advent of machines which took over much of the skill formerly supplied by the craftsman mass production approximating what we know today did not exist.

Even the power driven machines in the woodworking and metal working industries were essentially tools which helped the craftsman more than hand tools could. They were not at all of the nature of the present production machines which demand but little skill in their attendants.

In considering the history of production, it is a common mistake to think of mass production as bursting nearly fullfledged upon an eagerly waiting business world. That is not what happened. It was a growth, rapid in some industries, as we have seen, very slow and gradual in others. In some it has not arrived even yet, and quite properly so.

Effect of Taylor's Work. The big growth in the application of mass methods to industries to which it had formerly not been thought applicable came really as a by-product of Taylor's investigation of feeds and speeds in metal-cutting operations.

As a result of the time studies he made on machine tool operations he discovered that many useless motions were made and also that great economies could be realized from the subdivision of operations, making possible the great specialization of men and machines as well as repetitive operations. Men of vision saw the possibilities of this plan, and forthwith began to experiment with its application to many other industries.

So obsessed with the possibilities did these enthusiasts become that they naturally carried the ideas to extremes, attempting at times to apply mass methods to jobs for which they were not fitted. But the vision of those early experimenters with mass production brought about developments which have not only made mass production possible in industries to which it is fitted, but greatly improved the efficiency of production in operations that cannot be put on a mass basis.

The first step of this sort was the *improvement of power generating and distributing devices* which made cheap power available in needed quantities at any point within reason. Today the electric current, which is of course the most used form of industrial power, can be controlled almost perfectly, transmitted over long distances and subdivided to an almost infinite extent.

Next in importance probably were the *engineering developments and refinements in power tools and in measuring devices* which made it possible to produce products to an almost unbelievable degree of accuracy. Without this accuracy of dimension interchangeability would be impossible.

The rapid advance in *knowledge of industrial chemistry* was also an important factor.

Basis of Real Mass Production. All of these steps were leading to the development of a real philosophy of mass production, the basis of which was, as I have said, the breaking down of the fabrication of a product into its elements, so that one workman performed a single simple operation over and over. Parenthetically it is to be noted that later on many of these elementary operations were grouped both to increase the speed of production, largely with automatic machines, and in order to reduce the handling of material.

The Single-purpose Machine. It is not surprising that we find great emphasis being placed upon the development of single-purpose machines which performed only one or at most a very few of the simplest operations on a product and which could not be readily changed from one product to another. Some of them were specially designed for a certain product and could not possibly be used on any other. For a time the single-purpose machine became, especially in the metal-working trades, practically the god of the mass-production enthusiast.

Then came an unpleasant surprise. The American consuming public began to demand radical and frequent changes in the style of most of the things it used. Such changes in style or construction immediately make many of the highly developed single purpose machines obsolete. Mass production to be most effective depends upon mass distribution which will enable the machine to be kept busy continuously at maximum capacity with comparatively little change in the product.

Ford had built up an admirable system of mass production utilizing single-purpose machines to the practical limit. All went well until the public voiced its demand for changes not only in the appearance of the Ford car but for even more radical changes in its mechanical construction.

The single-purpose machines in the plant and *the plant itself, which was the very essence of a huge single-purpose machine*, were inflexible. To meet the new demands the entire factory had to be revamped and a large part of the machinery junked at an expense variously estimated at more than \$100,000,000. Considering loss of profit during the change this is probably a conservative estimate.

This and other lessons shook the faith of the enthusiasts in the universal applicability of mass methods of production.

Four Types of Production. It is now apparent that there is a place for four distinct types of production in the business world and that each type calls for certain kinds of machinery and equipment and a plant layout best suited to its particular needs.

These four types are:

1. Hand work or craftsmanship.
2. Job production, the artisan type of work but utilizing machines and power.
3. Job mass production.
4. Mass production.

To explain: There is today very little pure *handicraft production* in which power is utilized to only a negligible extent, most of the work being performed with hand tools. Cases in point would be the making of replicas of antiques and of highly artistic pottery. The graphic arts themselves are the principal places where the workers are not only artists but craftsmen as well. Such are the sculptors, painters, etchers and so on. There are also some craftsmen in the building trades who persist in hand work although in many cases they could, if they would, utilize power driven tools.

Under *job production* I include small jobbing foundries and machine shops which work practically solely on special jobs or repair work, small garment-manufacturing plants, the production of highly styled apparel and specialty fabrics, job printing plants and the like.

There is nothing approximating mass production in this type of plant. The workers are often craftsmen who are advanced enough to utilize power driven tools to a greater or less extent. No two jobs may be exactly alike and long runs on a single product are unknown. Therefore there is no place in a shop like this for highly specialized single-purpose machines.

However, there is apt to be a more or less regular sequence of operations, no matter what the product may be. Therefore, it pays to give some thought to the most convenient layout of equipment so that even on special jobs there will be as little handling of material as possible.

Under *job mass production*, I classify those plants which will run for a comparatively short period on a single product using mass methods, but which then change over their machines to turn out another run of a more or less different product. A book-printing plant would be an example; so would textile mills which make only a comparatively small amount of each kind of cloth, and furniture factories which may operate for several days or even a few weeks on a certain design of chair and then change over to another. A very large part of all American production is of this type.

And it is in just this type of business that very expensive mistakes have been made by trying to adopt mass methods in their entirety, including single-purpose machines. While it pays to lay out the plant logically considering the probable sequence of operations, the plant and its equipment must be kept flexible so that it can be adapted to change of products.

It is of the utmost importance that those concerned with production determine at the outset for just which type of production their particular business calls. Much of the existing inefficiency of production is due to failure to make the correct decision. It may be just as disastrous to try to apply mass-production methods to a product that is not suited to it as to fail to make the most of mass methods where they are suitable.

A great many products are made in what are practically job shops that could readily enough be made by highly refined mass methods. On the other hand there are far more products that are being turned out by mass methods at the present time that should be made by job mass methods, and that if so manufactured could be reduced notably in cost.

The lowest cost will be achieved only when the factory layout and equipment are perfectly suited to the peculiarities of the product. I can scarcely stress that fact too much, for anyone with a wide experience in factories and who subjects what he has seen to careful analysis must realize it. Yet it is far too seldom realized.

Misapplication of Mass Methods. Let us consider the misapplication of mass methods in somewhat more detail for unless the considerations underlying its use are clearly understood there is little good in studying the detailed problems of plant layout and equipment.

It is important to realize that while single-purpose machines were developed to meet the needs of mass production, the mass production itself is the expansion of the single-purpose machine idea. Looked at from the broader point of view a factory is a machine for the production of certain goods which, if mass production is to be used, must be a single-purpose machine. So if you have set up a factory as a single-purpose machine you are bound inevitably to mass production. This may prove to be a most expensive mistake in the case of a sudden change in design or style of your product.

It is also exceedingly dangerous to set up a factory for mass production of a product that is still in its promotional or even early commercial stage. Such a product should rather be turned out by job mass production, using to the utmost standard multipurpose machinery.

Take electric refrigerators as a horrible example of mass production entered into on a large scale before the time was right; that is to say, before the style and engineering features had been definitely and finally determined. It was some years before the public had enough experience with this radically new product to make up its mind as to just what it wanted in the way of an electric refrigerator for domestic use. Likewise it took time for the engineering features to be finally determined. But the manufacturers, obsessed with the mass-production enthusiasm, proceeded to set up their plants on that basis and naturally developed a number of single purpose machines which promptly became obsolete with the development of new types that better suited the public taste and with the working out of more economical factory methods.

The radio industry when young suffered from much the same mistake. Receiving sets at first were highly complicated devices, and usually enclosed in luxurious and very expensive cases. Mass production with its quota of expensive single-purpose machines was generally adopted at the start. But with improvements in the product, simplification of mechanism and the demand for less expensive sets, the entire design of the product changed and factory equipment in large part became obsolete. Had a compromise been made at the start and standard machinery installed which could have been easily changed to make other designs of product the great losses due to changing over the plants would have been obviated and doubtless the whole radio industry would not have seen so many sad days.

In the development of any plan of production consideration must be given to the supervision that the plan will call for and the supervisory talent that is available. For instance, I have seen plants so organized as to require a \$50,000-a-year production executive, while had the production been organized along different lines a \$10,000-a-year production man could have achieved comparable results. This is usually due to a mistaken desire to secure absolute perfection in production performance and sometimes to a desire for glorified records of performance.

Choice of Type of Production. Needless to say it is usually not difficult to determine at the start whether a product shall be made by method 1 or 2. The trouble usually enters when it is necessary to decide whether method 3 or 4 is best suited. So far we have spoken briefly of the considerations inherent in the product itself, and in the likelihood that changes in style may affect production. There are however many other important considerations which call for not only the best of engineering and production skill but knowledge of and the ability to forecast the market as well.

As an indication of some of the other factors that help to determine whether mass-production or job mass-production methods shall be used consider the situation that exists in two factories of a large shoe manufacturing concern.

Plant A is located in a city where highly skilled machine operators are available but where the scale of wages is high. Even with the most modern labor-saving machinery and equipment it is not feasible to make low-priced shoes in plant A, for the high wage rates make the cost too high.

Plant B, on the other hand, is in a small country town where wage rates are low. The workers, however, are not nearly as skillful as those of plant

A. They would be entirely incapable of using the modern equipment with which Plant A is equipped. Therefore it is out of the question to utilize this low-wage labor in the making of fine shoes.

It is important in deciding upon how the product shall be made to keep clearly in mind just what is the relation of production to the rest of the business structure. The ideal aim is to produce a product of the requisite quality, at the lowest possible cost, with a minimum of waste, paying the highest feasible wages and securing delivery in accordance with the reasonable requirements of the customers.

There are a multitude of factors governing this as we shall see in future chapters, but basic and underlying them all is the sound decision as to just which of the four possible types of production is best adapted to the product, taking into consideration all other factors.

CHAPTER II

ORGANIZATION OF THE MANUFACTURING DIVISION

BY PERCY S. BROWN, *Partner, James O. McKinsey & Company*

Organization, regardless of the place it occupies in an enterprise, is effected in order that the most efficient performance of the activities necessary to attain the objectives of the business may be secured. If this is to be done it is, of course, necessary that responsibility for the performance of these activities be fixed, and that the activities themselves be grouped in some manner so that when responsibility is fixed it will be based on some logical relationship of one group with another. In classifying or grouping activities the following objectives should have careful consideration:

1. Each group should comprise those activities which require a similar type of ability or training so that the executive in charge may become an expert in his field.
2. In so far as possible the executive heading up the group should be convenient to the place where the activities are carried on, in order to be in close contact with those responsible for performance and at the same time available for consultation.
3. In order that the group executive shall have the greatest possible freedom from detail, the number of subordinates reporting directly to him should be as few as possible, consistent with the needs of the enterprise and the effect that such an arrangement might have upon expenses.

These principles are applicable to the organization as a whole and not merely to the productive part of the organization. Therefore, we find an organization created in such a way that major functional groups are first determined. Common practice has divided the first groupings into financing, making, selling, and to these it is not unusual to add research and industrial relations or personnel management. Under these major groupings will be found the important functions of accounting, budgetary control, office management, controlling, designing, manufacturing, purchasing, selling, advertising, making market analyses, forecasting, hiring, guiding employee activities, etc. In turn these groupings are still further broken up into functional activities. It makes no difference how the organization be charted, or even if it has no organization chart, the fact remains that in operating the business, regardless of what it may be or what product may be manufactured, these functional activities do exist. One man may perform a half dozen of the functions in one organization, while in another six men may be needed.

Later in the chapter the relationships existing between the manufacturing division, which is the only one that will be covered in detail, and other divisions will be covered in a general way because of their inter-dependence.

Establishing the Manufacturing Division

In proceeding to create an organization to carry on the productive part of the enterprise, seven distinct steps should be taken:

1. Functional Activities. As soon as plans are made to begin the manufacture of some product it is immediately recognized that plant, machinery, equipment, tools, operators, clerks, foremen, etc., must be provided. Then the personnel will be expected to do certain things, some to perform actual work on the product, some to plan, some to record, some to inspect, and so on through the many activities connected with making any product. These activities we call functions, and in this chapter we deal with those functions connected only with productive operations.

As shown in the first part of the chapter, there are many functions related to production, such as cost accounting, personnel selection, purchasing, but in this chapter we will assume that the right raw materials and supplies are bought, the right kind of plant and machinery available, the personnel carefully chosen, cost accounting provided for, etc.

Our main manufacturing functions then will have to do with the plant or factory, machinery and tools, materials, production plans, personnel and their payment, methods, quality control or inspection, and the actual making of the product. All of these functions and their subdivisions are found in any manufacturing enterprise, no matter what form the organization may take.

2. Type of Organization. Having determined upon the functions that must be performed it then becomes necessary to decide upon the type of organization that it is thought will prove the most effective for their performance. The traditional type of organization is that known as the line or military type. This is disappearing from industry and therefore need not be discussed here. The most commonly accepted type of organization is that known as the line and staff. In its original conception this type of organization consisted of a line organization, from which certain activities, which might be classified as highly specialized and either advisory or in the nature of research, had been removed. These specialized activities, like research, engineering, etc., inasmuch as they did serve or could serve a large part of the organization, became staff activities, with much or all line authority withdrawn. In actual practice, the line and staff organization does not function as it was first conceived, rather it is a combination of that and the functional type. Perhaps it would be more correct to avoid calling the organization by any identifying term, and if this should be inadvisable to originate a new one such as functional and staff organization, or something else descriptive of what the organization actually is.

It does not seem necessary, in this chapter, to enter into lengthy discussion on types of organization, as management literature is replete with information—although much of it is confusing—and with organization charts. If functions are defined, and their relations understood, it is not difficult to show them graphically, regardless of what the organization type may be called.

3. Grouping of Functions. Once the functions have been outlined and the type of organization determined upon, it becomes necessary to relate the

functions to each other. The first step then would be to begin with any one of the major classifications, and for an example we might select quality control. In most instances quality control will consist of four functions: inspection of raw materials, inspection of purchased parts, inspection of parts or materials in process, and inspection of finished product.

The main functional group, quality control or inspection, quite clearly embraces the four subgroups as they are obviously closely related, but it cannot be expected that the technique of grouping functions is such that a fixed rule will apply. Opinions vary, of course, but the important thing is to arrange logical groupings as a basis for the next step.

In charting the quality control functions we would show the chief inspector or head of quality control division, and then connected in line authority below would be the four major functions of inspection. If we were selecting the personnel for these functions we might have, in the case of a small enterprise, the chief inspector functioning as head of the department and of finished product inspection, and another man in charge of raw material, purchased parts, and parts or material in process inspection. In a large organization all of the functional groupings would be headed up by specially qualified men under a chief inspector at the very start.

In considering functional groupings it is necessary also to take into account the question of location as affecting the performance of the work. Let us take the planning function as an example. In scheduling, routing, and moving materials and parts in process we would be faced with a choice of either fully centralized operation or partly centralized. We would probably find very quickly that more effective results could be secured if the major planning function were centralized, with records of a permanent nature, planning boards, and clerical functions which are performed in relation to all planning and not to purely departmental planning activities, all in the central planning office. But those service functions having to do directly with production department activity would be decentralized and "planning centers" or "flow centers" would be set up to serve individual departments or groups of departments so located that they could be effectively served from one center. These centers would perform that part of the planning that has to do with seeing that operators are rung in and out of jobs, work issued, received and counted, schedules for the specific departments followed, etc. Regardless of the plan followed, the functions themselves would be closely related from a group standpoint and the problem of the extent of decentralization would be considered from the standpoint of size of organization, size and location of departments, etc.

These examples are given merely to emphasize here the point that grouping of functions is important, regardless of just how the groups may later operate.

4. Functional Responsibilities. The groups being determined, it becomes necessary to define carefully the responsibilities of each. This can best be done through Standard Practice Instructions, which may be simple or elaborate. The primary requisite is to reduce to writing exactly what is expected of each group, not only what they do, but what their relationships are with other groups. Instructions defining responsibility would be issued for the time study, methods, scheduling, routing, inspecting, and all other group

functions and at the same time would state just what relationships would exist between these groups and all others that they serve or with which they come in direct or indirect contact. The rate setting section would have close relationships, from a staff but not from a line standpoint, with all manufacturing and many service departments, with foremen, operators, clerks. It would have similar relationships with the pay-roll department, cost department, engineering department, purchasing department, and others, because it would be performing or requiring services from them in varying degrees. The responsibilities in relationships, large or small, should be defined as concisely as possible but as completely as necessary.

5. Functional Authority. Where responsibility is definitely fixed it should be accompanied by such authority as may be necessary in carrying out the work. This does not mean that all responsibilities need authority, but that to hold a man responsible for kinds of work where he must instruct, lead, and, if necessary, order others, he must have the authority that will make his work effective. A foreman, for example, has fixed responsibilities no matter what type of organization he works under, and he must have the authority to accompany it. A clerk in the stores department, on the other hand, has the responsibility for posting accurately all withdrawals and entries of materials in the balance of stores ledger and needs no authority to accompany this responsibility.

The functional type of organization proposed by Frederick W. Taylor defines functional management as follows:

Functional Management consists of so dividing the work of management that each man from the assistant superintendent down shall have as few functions as possible to perform. If practicable the work of each man in the management should be confined to the performance of a single leading function.¹

When Frederick Taylor wrote this definition the only type of organization in general use was known as the "line" organization and the step from that to a purely functional type was a big one which few organizations took at the time or subsequently. Taylor, it will be remembered, provided for eight functional foremen, four in the shop and four in the planning room. Each of the eight was to have direct authority over each operator in specific functions. The four in the planning room were the route clerk, instruction card clerk, cost and time clerk, and disciplinarian; and the four in the shop were the speed boss, repair boss, inspector, and the gang boss. Here there could be no overlapping of authority as each function carried full line authority, but only in relation to the functional activity.

But in other types of organization this overlapping does occur. Every foreman, for example, in a line and staff type of organization performs work connected with personnel, planning, engineering, inspecting. If all of these be classified as staff functions then the foreman inevitably is forced by circumstances to do some work in these categories, because otherwise he would not be able to "produce."

¹ TAYLOR, FREDERICK W., "Shop Management," p. 99, Harper & Brothers.

The same procedure that sets up standard practice instructions for responsibilities should be followed in relation to authority. If properly done the two will be handled at the same time and the instructions will cover both points. It is easier to place responsibility and at the same time state clearly what authority, if any, accompanies it, than to state the former and leave the latter to be added later or covered in a separate instruction.

6. Establishing Policies. This is a matter of related activities. Policies must be announced and understood, for example, in relation to hiring, placing, transferring, or discharging operators. They must be formulated on the broad relationships of the entire planning organization to production departments, of the works engineering department to other departments, etc. Many of the policies will originate higher in the organization than the manufacturing group, and will serve as a basis for manufacturing policies, as well as those of other departments of the enterprise. Though some of the policies will also be clearly defined in standard practice instructions, in relation to contacts between specific departments, they must also be clearly understood as relating to the entire organization.

7. Selection of Personnel. Knowing the functional groupings, and their responsibilities and authorities, it then becomes necessary to fit the personnel to these groups. It is unnecessary to go into detail as to how it should be done and one example will suffice. Let us take the example of the quality control or inspection function. It will be clear that for raw materials control, if only weighing, gauging, and measuring are necessary, a man with no particular training would be satisfactory, but if specifications were in force calling for chemical analyses of the materials a skilled chemist would be needed. An organization that scientifically goes into the matter of organization, will, in all probability, have job specifications made at this point. Then the personnel department will make its recommendations, discuss them with the proper department heads, and take the necessary steps to provide men and women who have the required ability, experience, and personality, either from within or without the organization.

We now have the basis for an organization chart, not because we are particularly interested in a chart but because we must in some way picture just how the functions and the personnel are related to each other. Probably no two manufacturing enterprises will approach the charting in the same way, even if they are relatively of the same size and make identical products. Therefore, organization charts are avoided here; if one were shown it would be merely the author's personal opinion as to what might be best for some specific organization. Perhaps the person who would undertake the chart would call the head of the manufacturing department the works manager, perhaps the production manager. Then he would decide to have an engineer in charge of all plant engineering functions as well as machinery and tool design and manufacture, while another man would decide to have two departments. It is immaterial from the standpoint of what we are after at the moment—the picturization of the organization with which we intend to work. The picture will show functional relationships and the personnel, and the standard practice instructions will define relationships, responsibilities, and authorities.

Now we are ready to begin work, but some of the personnel will be used on productive work, adding to the value of the product by work actually performed upon it; others will be engaged in what might be termed "service" or "staff" work, such as planning, engineering, etc. Immediately we must consider how we can most effectively use this personnel.

It would seem logical that we must have our manufacturing departments properly laid out in relation to each other, and then within the department we must have machinery and work places laid out as scientifically as possible. We may group our departments by specific character of work performed, all punch presses in one department, milling machines in another. Or, if we use only a few milling machines, we may group them with drill presses and tapping machines. Then we will route the work through in proper sequence and in some cases have it travelling back against the forward flow. A manufactured part might be drilled before japanning, but tapping might be postponed until after japanning because the filling in of a tapped hole with japan might necessitate retapping. Or two different parts making up a subassembly might flow through until each is completed and then have to go for assembly to a punch press, a spot welder, or a riveting machine in another department. In many industries this has led up to a wise modification in the idea of complete departmentalization. In such organizations special-purpose machines, regardless of kind, are set up in the department where the work can be most effectively performed and "back tracking" is thus eliminated. Undoubtedly many cases could be found where one department is carrying on many varied machine operations efficiently. Size has much to do with this because what might be good practice for a large organization would be impracticable in a small one. The large organization, for example, could have punch presses, drill presses, spot welders, etc., in a bench assembly department and enough of them so that skilled set-up men and instructors, acting as assistants to the foreman, could be employed. In a small plant where perhaps only one of each of these machines would be used in this special department, it would require a rarely skilled foreman to handle the situation as the expense of having competent assistants would not be justified. In the latter case it would be more economical to keep the departments highly specialized and accept the back tracking as necessary. No fixed rule can be laid down as to optimum size of department, character of work that it should perform, or amount of supervision and instruction necessary.

Coordinating Departmental Interests. When factory organization is discussed it is essential that consideration be given to methods of coordinating departmental interests. At best, the possibility of friction always exists between those departments engaged in strictly manufacturing operations and the departments serving them. This holds equally true also of relationships between departments like engineering and planning. The difficulty of eliminating friction and misunderstanding between the functional foremen, under the Taylor functional foremanship plan of organization, is probably one of the most cogent reasons why functional foremanship has not been more widely adopted. Although each function is specifically defined as to responsibilities and authorities for each "boss," and carefully prepared stand-

ard practice instructions issued, yet clashes occur between the functional bosses themselves, and the men working under them are confused and sometimes irritated by having so many men "butting in" on their work. It is not that the basic principle is wrong but merely that we seem not to have progressed to that point where management can effectively use this kind of a tool, because management finds it more difficult to handle and, other ways being easier and yielding satisfactory results, other ways are adopted. No fine policies, no standard practice instructions, can perform the entire service, can insure an interrelation of functions, an integration of interest and full cooperative effort. We are still dealing with human beings as they are and not as we would like to have them be.

During recent years considerable discussion has taken place as to the part that "consent" bears in all industrial relations. We are more and more inclined to measure the quality of leadership in management by the degree with which it effectively "sells" itself to the entire operating group, regardless of position or responsibility. We use this expression selling rather loosely but mean by it that ability which one has for convincing others that the plans, methods, or what not, that are being discussed or promulgated are such that they will be glad to follow them. It would seem therefore that selling oneself to the organization is in fact securing their consent to what we wish done. This may be one of the reasons why the purely functional type of organization is not more widely used. It has not been properly sold, or, to put it in the other terms, consent has not been secured. If this be true, it places the responsibility directly on management. But if management finds that a modified form of functional management is effective for the purpose, less difficult to handle, it cannot be blamed for adopting the easier way. Any modified functional or staff type of organization, to be most valuable, must provide some means for coordinating the functions.

One of the recognized means of coordination is the committee, which provides an opportunity for a periodical organized opportunity for a meeting of the minds. But to be effective the committees should meet no more frequently than is necessary to supplement individual contacts, agenda should be planned in advance whenever possible, discussion should be free but orderly, and never should the meetings run along as debating societies, as they so frequently do when some few men with opinions and a flare toward oratory attempt to monopolize them. Organized to meet actual needs and used properly, committees are important and necessary; organized or used improperly, they are worse than none at all. It is a test of management as to what value they can be to the organization.

Relationship to Other Divisions. One other important organization matter should be given consideration—the relationship between the manufacturing division and other divisions of the enterprise. Manufacturing depends on the sales organization for the information that enables it to function. If the sales organization does not supply timely information as to anticipated sales, the manufacturing and purchasing organizations cannot hope to function at their greatest effectiveness. It seems obvious that with complete harmony and understanding between the sales, and manufacturing and purchasing organizations, the manufacturing organization can be put in a

position to plan its production so that it will always have the right goods of desired quality on hand when wanted, in the right quantity, and at advantageous cost figures. But in industries faced with wide seasonal fluctuation it is not always possible to do this. In such cases experience has shown that the production curve can be flattened to some extent when the sales, manufacturing, and financial organizations put their heads together and plan what can be done in the way of financing, manufacturing to stock, and carrying in stock for an agreed period. Industry at large needs more of this kind of cooperation, and is learning that one of the most effective ways to secure it is through budgetary control, which forces coordination, directs attention periodically to weaknesses, opportunities, excesses, accomplishments, or wasteful practices. The complete budget, by all departments of an organization, is probably the best means available for creating conditions favorable to departmental effectiveness through coordination and mutuality of interests, while at the same time accomplishing the best results for the company as a whole.

CHAPTER III

THE INDUSTRIAL PLANT

BY ROBERT P. KING, *Engineer, DuPont Rayon Company*

The planning, design, and construction of the modern industrial plant cover such a wide spread of size, product, permanence, and other variables that only general considerations can be indicated in this chapter. Each industry and organization has its own special problems, and even elements common to all industry must be evaluated to determine their degree of importance in a given case; for example, water supply is a vital consideration in some textile and paper plants, often proving a deciding factor in settling location, production costs, etc., while a foundry or machine shop finds this an unimportant element. Then, too, the problems of altering or extending an existing plant are quite different from those involved in locating a new plant, since many factors (like building arrangement, power supply, etc.) may be determined by existing facilities. This discussion follows the procedure involved in providing a new plant, with its usual accessories, indicating the important points to be considered by the management and detailed by the technical consultants.

Location. The factors to be considered in selecting a location for a plant may be grouped as:

A. Geographical (relating to general choice of state or city).

B. Local (relating to specific sites within a given area).

The considerations involved in geographical location include

1. Market.
2. Raw materials.
3. Labor supply.
4. Power and fuel and water supply.
5. Transportation.
6. Climate and other physical surroundings.
7. Public relations (legislation and general attitude toward industry).
8. Prestige or advertising value.
9. Financial conditions, banks, etc.
10. Service industries.

Among the factors influencing *local location* are:

11. Rural, suburban, or urban.
12. Character of site (shape, contour, etc.).
13. Room for expansion.
14. Public services and utilities.
15. Building restrictions.
16. Labor supply.

17. Smoke, dust, odors and noise.
18. Waste disposal.
19. Land values.
20. Taxes.
21. Services: mail, express, telephone, telegraph, etc.
22. Supplies, repair service, etc.

1. *Market.* Some industries are equally adapted to all locations (*e.g.*, laundries, bakeries, printing), though many of these are now affected by improved transportation, advantages of centralization, etc., (*e.g.*, preparation of food stuffs like meat and ice cream). It is usually preferable to produce near the marketing point commodities having large bulk or weight and small value; otherwise transportation costs may be too high. Products manufacturable without reference to local market include those of high value and small bulk or weight, involving extensive organization or equipment, and requiring frequent changes in design.

2. *Raw materials* analysis includes: quantity and quality available and required, reliability of source, transportation costs, whether supply is monopolized or competitive, and possible future trends both in the supply available and the probable needs of the industry (*i.e.*, use of substitutes, etc.). Careful study is particularly important where the raw material is a product or waste of another industry rather than a basic raw material; very rapid and fundamental changes are occurring in the availability of certain materials.

3. *Labor supply* is a less difficult problem than formerly, with the advent of automatic or semiautomatic machinery in many industries, reducing the time required for training craftsmen. In many cases, favorable results are obtained by developing the labor force by a suitable training program, without attempting to recruit skilled help. Semiskilled or unskilled labor is obtainable almost anywhere. The character of the local population may affect its suitability for a given industry, but this factor is less important than formerly, with freer movement of labor from place to place, and industrial development in nearly all sections of the country. The effect of environment on the supervising force is quite important; *e.g.*, such factors as urban advantages, recreation, schools, etc. The labor situation may be undesirably affected by near-by industries having violent seasonal or other fluctuations in activity. The status of labor organizations in a given locality is, of course, an important matter.

4. *Power, fuel and water supply* vary in importance with the need of the industry. The power situation is rapidly becoming more uniform with development of transmission facilities for electricity and pipe lines for gas and oil. The question of central station power vs. isolated plant is discussed below. In analyzing the comparative merits of various locations, definite proposals or contracts should be obtained from suppliers of these commodities, defining all factors influencing price and the details of facilities provided, *i.e.*, whether the power service includes transformers and switching equipment, whether lighting energy is billed at power rates, the extent of coal, power factor, demand, and other clauses, etc. Reliability of service, including probability of interruptions, is a very important element, particularly for industries having inherently continuous processes involving considerable

loss in case of shutdowns. The situation may justify services in duplicate, or some other emergency supply.

For water supply, some industries require closely controlled quality (chemical analysis) and enormous quantities—in others, water supply is a minor item. Coupled with this problem is waste disposal.

5. *Transportation.* Reliable facilities are particularly important in these days of low stocks and quick turnover of raw material and finished product. The best plant location from a transportation standpoint is the one which results in the least total cost of raw materials in, plus finished products and by-products out. In many cases, the freight rates are lower for raw material than for finished product; in some cases through freight rates or other peculiarities of rate schedules are unusually favorable to certain localities. It is particularly desirable to locate with switching service from more than one railroad, or on a belt line connecting with several railroads; such competition not only tends to lower freight rates, but to improve general service. Besides rail freight (including package cars, LCL container service, etc.), express, automobile trucks, and now airplane routes must be considered. The regulations of the railroads, and what they offer in the way of siding construction and maintenance, are important to develop before deciding on a plant location.

6. A number of more or less important elements are suggested under *climate and other physical surroundings*. Temperature and humidity can be controlled by suitable building construction and equipment, but at considerable cost. Temperate and reasonably even climatic conditions not only materially assist quality and uniformity of product, but increase output by keeping the health and vigor of the working force at its best. A region known to have unhealthy conditions, such as malaria, is not likely to be desirable.

7. *Public relations* include such factors as state labor laws (working hours, workmen's compensation, factory building codes, employment of women and children, minimum wages, employer's liability, etc.), taxes, and the general attitude toward industry. In some stages an unreasonable attitude of union labor has resulted in embarrassing legislation, of no permanent value to those whom it was supposed to protect. There may be a great difference between the laws, or degree of enforcement, in adjacent states or even municipalities, resulting in difficulties of competition between comparable industries. Municipal regulations affecting plant location and operation include building codes, zoning restrictions, ordinances limiting smoke, noise, dust, odors, etc., disposal of sewage and waste, taxes, and the like. A favorable public attitude may result in inducements offered to a new plant such as free site, exemption from taxes for several years, aid in financing, and preferential purchasing of product.

8. Certain localities have become so widely known as preeminent in a particular industry that considerable *prestige or advertising value* has been attached to this location. Examples: Grand Rapids (furniture), Trenton (pottery), Sheffield (cutlery), etc. With the extensive changes during recent years in general locations of industries, this factor has decreased in importance.

9. *Financial conditions, banking facilities, etc.*, have little effect on the general location of an industry, since financing is no longer a local or even regional problem. The handling of pay rolls and other local financial questions do require some consideration.

10. Some plants, particularly small ones, require *service industries* such as foundries, machine shops, maintenance and repair work, etc., as an adjunct to the business, to avoid setting up too extensive organizations within the plant. The larger industries find it desirable, as a rule, to handle such work themselves. Where the need of such service is variable, or involves extreme peaks of activity at certain times, as pattern, die, tool, and fixture work for foundries, drop forging or punching shops, and machine shops, it is usually economical to depend on outside assistance, at least in part, rather than to have partially idle buildings and equipment, and excessive labor turnover. The same principle may be applied to manufactured parts—the automobile industry is a good example.

11. Among the local factors, *urban, suburban or rural location* involves a number of considerations. The general trend seems to be toward suburban or rural locations, particularly for the larger plants, which can develop their own communities. The situation involves many investments and responsibilities besides the plant itself, such as housing, community services, and recreation, the value of which depends upon resulting advantages such as improved labor conditions, greater loyalty of employees, and freedom from undesirable surroundings. *Rural* location usually offers lower expense for land, buildings, and taxes, fewer restrictions, opportunity for expansion, lower living costs and wage scales, freedom from labor union influence, and less tendency to labor turnover. *Urban* locations have grown less attractive to the working force, due to development of automobiles, good roads, radio sets, and motion pictures. As a rule seasonal, or other non-stable industries are better in urban or suburban locations, with a larger labor reservoir, although winter industries can sometimes fit in with a farming population normally idle at that season. Among the types of industry naturally suited to urban conditions are: small plants, requiring local market or depending on other industries for supplies or service; those requiring convenient access by buyers, and hence naturally grouping themselves within a limited area (e.g., the clothing industry in New York City); those requiring mostly female labor, naturally recruited from the families of other industrial workers, and more easily obtained if the plant is convenient to the residential district. For many types of industry, locations like the Bush Terminal in Brooklyn or the central manufacturing district of Chicago offer a number of advantages; receiving, shipping, storage, power, maintenance, and other services can be shared among a number of plants, allowing the management to concentrate on its production and marketing problems with minimum capital investment and operating responsibility.

Suburban locations present many of the advantages of both urban and rural sites, particularly for medium-sized plants; there is a marked trend toward industrial suburbs of large cities (e.g., Cincinnati, Cleveland, Newark), with factories adjacent to residential districts in the outskirts of the city.

12. *The character of the site* merits careful consideration, including shape of plot, contour, drainage, whether filled or natural ground, access by road, railroad, and water.

13. *Room for Expansion.* Many of these elements are not limiting ones, and can be met by proper planning, but there may be large savings in construction and operating costs (such as material handling) resulting from a desirable site. Protection of the plant against intrusion, fire, flood, etc., from without is important; the deed or lease covering the property should be examined for incumbrances such as public rights of way and limitations as to use, besides the usual questions of mortgages, liens, and flaws to title.

14. *Public services and utilities* include electric power, gas, water, sewers, rail and water facilities, fire and police protection.

15. *Building restrictions* (as outlined under 7).

16. As far as *local labor supply* is concerned, there is not so much difference as formerly between one location and another, due to increased use of automobiles by employees. However, adequate public transportation facilities—trolleys and buses—are important.

17. *Smoke, dust, odors, noise*, and other so-called "nuisances" must be considered both from the standpoint of the effect of outside conditions on the plant in question, and that of prevention of objectionable features of this plant. This element is increasingly important with the advent of plants in residential sections and stricter enforcement of municipal codes.

18. *Waste disposal* (both solid and liquid) is in the same category; for plants like foundries the disposal of slag, etc., is a real problem, unless there is filling needed nearby. Combustible refuse can be burned in incinerators or (if the quantity is sufficient) in boiler fire boxes of suitable construction. Many cities have regulations forbidding disposal of inflammable or corrosive liquids into public sewers.

19. *Land values* are usually of secondary importance in selecting plant location, since even moderate operating advantages outweigh reasonable differences in first cost of site.

20. *Taxes* are seldom a deciding factor, unless high rates are coupled with excessive industrial valuations, or unless local taxes are supplemented by state taxes on income, capital investment, or excess profits.

21. *Services* such as *mail, express, telephone, telegraph*, etc., should be assured according to the particular needs of the plant.

22. *Supplies, repairs*, and the like should also be assured according to the particular needs of the plant.

Specific information regarding certain locations and industries can be obtained from:

United States Census reports.

United States Department of Commerce reports.

Railroad and power company bureaus or industrial agents.

Chambers of Commerce.

General Arrangement, Planning. For building a new plant, or materially enlarging an old one, the following *schedule* is desirable, in the order indicated:

1. *Evaluate Production Program.*

Plant organization:

Character of product.

Quantity and variety of product.

Production operations, process, and equipment.

Future possibilities of change in character, quantity, or method of production.

2. *Plant Layout* (see Chap. IV).

Plant organization and specialist or consultant:

Space requirements and desirable sequences or relations of process operations.

Special requirements of equipment.

Material handling and storage.

3. *Buildings (Process)*.

Architect or engineer:

Type—floor space, interrelation.

Architectural and engineering design.

Accessories (see below).

4. *Buildings (Miscellaneous or Accessory)*.

Architect or engineer:

Administrative.

Power—steam and electric generation, etc.

Warehouse—receiving, shipping.

Service—cafeteria, medical, recreational, etc.

5. *Building Accessories*.

Architect or engineer with plant organization:

Heating, lighting, ventilating, and conditioning.

Sanitation (including waste disposal).

Transportation (elevators, conveyers, etc.).

Fire protection.

Water service.

6. *Draw Plans*.

Architect or engineer.

7. *Let Contract*.

Architect or engineer with plant organization.

8. *Build and Equip*.

Contractor.

Usually the plant organization can best *evaluate the production program* by thorough analysis preceding the actual design, except perhaps in a well standardized industry such as foundry, textile, etc. Such studies can be made by a planning department, a works engineer, or a committee of operating, engineering, and process or design representatives. Each department and process should be analyzed, first separately, then in relation to the others and to general facilities such as office and power plant, finally with regard to ultimate needs and possible changes. With straight-line production layouts, subsequent addition of operations often proves difficult, sometimes requiring complete rearrangement of equipment and involving limitations of floor space.

Building design work usually calls for assistance from an architect or engineer outside the plant organization—preferably a specialist in the particular field involved—based on the preliminary analysis by the plant organization, and subject to approval by the proper organization representative. In few cases is the final design literally proportioned to the preliminary outline; there are considerations of economical dimensions of buildings, of special adaptation to the site or surroundings, of future growth, and partic-

ularly of providing plant structures of sufficiently general usefulness that resale value and adaptability are assured. Sometimes the design as well as the construction is affected by need of quickly occupying portions of the plant, or of retaining use of adjacent facilities.

There has been a decided trend toward improved appearance of factory buildings, particularly exteriors. The basic consideration is, of course, suitability for production at reasonable cost, sometimes in minimum time. Decisions regarding beautification of buildings and grounds must be made on the merits of individual cases; however, a good architect can design a plant with some regard to appearance, proportions, and suitability, at little if any excess cost. Ugliness is not a proof of cheapness. Examples of what is possible in this direction are easily found in modern concrete structures; panels or contrasting surface colors or textures do wonders to such exteriors.

Standardized buildings are offered widely today in a variety of types, and of almost any size. The use of such structures eliminates the need of a consulting architect or engineer for building planning, although such services may be well worth what they cost. These buildings are useful for small plants and for such uses as the warehouse. Among the advantages of such buildings are:

Speed of construction.

Economy in time and expense of plans.

Minimum delay in securing material, constituent parts furnished from prefabricated stock.

Costs definitely figured and assured.

Designs already proved sound.

Some of the disadvantages are:

Cost; this is often apparent rather than real when floors, heating, lighting, sprinklers, painting, etc., are added; a capable analysis of the total cost is required.

Usually not ideal for any special manufacturing work—best where no unusual process conditions affect desirable building design.

Adapted to average climatic conditions, but perhaps not for the site chosen.

Sometimes uneconomical to heat, ventilate, and light, as they are often designed only from a standpoint of construction cost.

Eliminate the disinterested viewpoint and advice of architect or engineer, who has no incentive to use any particular design except the best for the job.

Building accessories are discussed below, also *contract* and *construction* problems. In some cases design and construction work can be handled by the same organization, with greater economy, simplicity and speed.

Types of Plant Buildings. Among the factors affecting choice of specific types of factory buildings are:

1. Nature of industry.
2. Nature of process and equipment.
3. Geographical location.
4. Economy in movement of materials.
5. Control of activities.
6. Value of land.
7. Permanence and resale value.

1. *The nature of an industry* includes considerations such as:

Continuous or jobbing manufacture. Will operations be segregated under separate classes (like lathe, screw machine, etc.) or consecutively in order of application to the manufactured article and is there need of storage space or allowance for unequal activity in certain departments?

One or several products, models, etc.: in other words variety and diversity in production.

Subassembly work and part storage, either produced or purchased; this includes inspection and other checking.

Seasonal or steady business: provision for acute peaks of activity such as Christmas trade; frequent rearrangement to meet changing styles of product.

2. *Nature of process and equipment* involves provision for fumes, heat, and other such conditions, and also for special, bulky, heavy, noisy, or vibratory machinery (e.g., drop forges) which must be specially housed in order not to affect other processes. Special foundations may be required, or extra head room. Highly combustible or explosive operations need buildings of abnormal construction.

3. *Geographical location* affects the type of building, and particularly the materials used, so that the plant may be protected against conditions of temperature, humidity, wind, insect attacks (such as termites).

4. *Economy in movement of material* requires attention to elevators, conveyers, trucks, receiving, shipping and storage facilities, particularly for bulky or heavy materials, or in processes involving much repetition of moving operations. Modern automobile plants, with their conveyer assembly lines, are a good example of such equipment, necessarily considered in building design.

5. The location of department offices and general plant arrangement to facilitate *control of activities* is of lesser importance; particularly in large plants, adequate production and incentive systems accomplish more than a foreman's unobstructed view of his floor.

6. *High land values* lead naturally to multistory buildings, and *vice versa*; such elements of building design as heavy walls, space between buildings for light and ventilation, etc., may be affected by high property costs.

7. *Permanence* often determines building character; temporary or easily alterable types are natural in an uncertain industry, perhaps even portable buildings. High-grade construction means not only greater initial cost but usually more difficulty and expense for alterations. It may be feasible, however, particularly in urban or suburban locations, to erect a plant suitable for the average industry, and therefore having a *high resale value*, without sacrificing any desirable elements for the particular original purpose. Modern types of buildings are affected more by obsolescence than depreciation; the real life of steel, brick, and concrete structures is not known, but depreciation is usually based on fifty years' life.

Specific types of buildings may be classified by:

Number of stories.

Type of walls.

Type of floors.

Type of roofs.

Single-story buildings are applicable (in a very general way) to:

- Inexpensive land.
- Sites amply large for expansion.
- Heavy materials or machinery, or severe vibration, or conditions requiring great solidity.
- Need of liberal ventilation.
- Floor areas greater than 80 to 100 feet in least dimension.
- Hazardous work, best isolated, and not above or below other operations—perhaps involving fumes, heat, etc.
- Greater flexibility of layouts, subassembly work, etc.
- Better supervision and coordination than several floors under one control.

Many of the advantages formerly claimed for single story buildings have been eliminated or much reduced by improved material handling (conveyers, power trucks, high-speed elevators, etc.) which may result in lower factory costs in a multistory building than in a single large floor area.

Improved building construction has made *multistory buildings* available for relatively heavy work; such buildings (besides the converse of considerations outlined above for the single-story type) may be:

Useful for manufacturing layouts permitting vertical transfer of work in progress (in many cases by gravity) or requiring no transfer between departments.

More free from street or yard noises, dirt, etc., particularly in cities.

Designed for vertical expansion by additional stories (particularly with flat-slab roof construction).

Equivalent to single-story conditions in the top floor on sites having considerable slope, permitting access at grade to upper floors.

As a rule, multistory construction (at least up to four- or six-story buildings) costs more per useful square foot than single story, but less per cubic foot for equal quality; a fair comparison must include stairs, elevators, extra wall thickness, etc. A very rough figure for moderate-sized single-story buildings of good quality is \$3 per square foot, twelve feet high, or 25 cents per cubic foot. Maintenance and operating expenses (heat, paint, roofing, etc.) are usually less for multistory buildings. The trend seems to be toward single-story structures, particularly for small plants. In many large plants, a happy combination of the two types can be made, using single-story buildings for heavy assembling and multistory for parts manufacture, offices and laboratories. Very effective plant arrangements can be made with alternate rows of single- and multistory structures, with roads and railroad sidings between (Fig. 1), or with continuous floor space on the first floor (Fig. 2).

Types of Walls. *Wood* is chiefly suitable for temporary or very small buildings, is comparatively short lived, combustible, and has little salvage value.

Metal (corrugated or other sheet construction) is useful for portable or small buildings, quickly and cheaply erected, non-combustible, and has fairly high salvage value. Such buildings are difficult to heat and have little strength as all loads must be carried on the supporting frame.

Brick is solid, durable, and adaptable to nearly all sizes and heights, easier to repair or alter than concrete, but has become more and more expensive

due to high labor rates. "Mill construction," with heavy brick walls and massive wood beams and floors, has been extremely satisfactory for multistory buildings. It is slow burning, useful for nearly all industries having moderate working loads, and altogether practical. It has become less used, not because

FIG. 1.

FIG. 2.

of inherent defects, but due to decreased relative cost of concrete and steel compared with wood and brick. For multistory buildings, brick walls unsupported by steel are extremely thick, reducing useful floor areas; then, too, this type of construction cuts down available window space because of necessary pilaster widths.

Hollow tile is extremely useful for small buildings, interior walls, or curtain walls of steel frame buildings. Its use reduces labor costs of construction materially. Tile has never been considered as good a fire retardant as brick, but it is being improved in this respect. As a heat insulator it is excellent.

Concrete or brick and steel (so-called "fire-proof construction") is the accepted type for multistory, and for many single-story buildings, having strength, economy of space, unlimited application as to height or area, good appearance, durability, and resistance to fire. The steel frame can be designed for any desired loads, and the walls serve only as weather protection and heat insulation. Such construction is relatively expensive but is easier to alter than solid brick or concrete. Reinforced concrete (without a separate steel frame) requires more thickness and is harder to repair or alter, but is well adapted to heavy buildings (such as warehouses) involving few changes in occupancy. The term fire-proof is a misnomer; brick, steel, or concrete is not immune to intense fires, particularly with severe exterior exposure or highly combustible contents in large quantities. Even with the best construction possible, fire protection and prevention authorities will urge sprinklers, fire walls, and other precautions.

Glass and steel (so-called "daylight construction") involves a structural steel frame with practically continuous glass walls, perhaps for almost the full height of each floor. While this gives excellent daytime light transmission, it is difficult to heat, and expensive to maintain, since glass requires more cleaning and repairs than brick or concrete. With increased reliance on artificial lighting, less value is attached to such construction, particularly for work involving night as well as day shifts. A certain amount of wall or pilaster area is useful in most factories, and glass area can be overdone as well as underdone. One large factory building is now under construction without any windows at all.

Types of floors selected should be:

Suitable for the machinery and process (fire hazard, dust, acids or alkalis, etc.)

Durable, with low maintenance.

Comfortable for workers, particularly if much standing or walking is necessary, or if women are employed.

Reasonable in cost.

Concrete has many obvious advantages and is widely used, but it is uncomfortable and tiring to stand or walk on, and may (unless laid with proper precautions) wear sufficiently to allow dust or grit to get into fine machinery. Such floors are difficult to cut for piping, wiring, machinery installation, etc. In multistory buildings, concrete floor slabs should have inserts provided during construction, to permit attachment of sprinklers, shafting, etc., on the ceiling below.

Wood block floors require a concrete base and are therefore expensive but are admirable in most respects, particularly for heavy work, long lived, quiet and comfortable. Vibratory machinery should be fastened through the blocks to the concrete below.

Wood plank with hardwood surface makes an excellent floor, particularly for light work but is increasing in cost compared with concrete. Machinery installation, cutting for piping, etc., is easy and inexpensive.

Asphalt, mastic and other special surfaces are applicable to wet, corrosive or other peculiar conditions.

In buildings with sprinkler systems it is desirable to provide floor drains or scuppers to the outside, to avoid excessive water damage in lower floors of multistory buildings. Where plant layouts are known at the time of construction, a permanent aisle marker can be set in the floor, to aid in orderly operation. Floors and walls should be integral, or tightly joined, avoiding baseboards or moldings, which are dirt and bug catchers. Wood floors should be tongue-and-grooved, side nailed, preferably with mopped roofing paper between planks and flooring, to keep the floors tight against dirt and water. Elimination of slipping hazards is important in many plants, and many methods are available to suit various conditions. It is extremely desirable to plan underground piping, ducts, sewers, etc., to be outside buildings wherever possible, and to be adequate in size and construction, so that costly and embarrassing changes may be avoided during operation of the plant.

Types of Roofs. *Flat roofs* (with or without a slight pitch for drainage) are least expensive in first cost and upkeep, but do not permit good natural lighting of building interiors more than sixty or eighty feet wide. Many multistory buildings now have dead-flat roof slabs, permitting additional stories to be built without disturbing the slab. The water standing on such roofs materially reduces heat transmission, thereby keeping interior temperatures more steady.

Peaked roofs are rarely used for factory buildings, except minor sheds, etc., of light construction.

Monitor roofs provide excellent construction for medium- or large-sized buildings; moderate in expense, satisfactory in lighting distribution if properly designed, and reasonable in upkeep cost. Such a design is particularly good where heat, smoke fumes, etc., must be exhausted, e.g., foundries and drop forges. Monitors are admirably adapted to cranes, railroad track bays of a large building, and other needs of high clearances.

Sawtooth roofs have been used extensively for textile, printing, and other industries requiring good and even light, the theory being to face the sawtooth windows north, avoiding direct sunshine and glare, and getting the comparatively uniform cloud-reflected light. Such construction is initially expensive and high in maintenance cost, difficult to heat, and usually no more satisfactory than a properly designed monitor type.

Roof-deck materials are: plank; concrete, often of specially light construction; sheet metal, including galvanized steel, copper, lead, aluminium, etc., in continuous sheets or shingles; asbestos or other prepared sheets; tile. In addition to cost and permanence, heat insulating value and resistance to fire should be considered.

Covering surfaces include: felt mopped with tar; asphalt or pitch, with or without a gravel or slag top layer; composition or ready roofing; sheet metal; asbestos. Each has its advantages. A plain mopped asphalt and felt

covering on well-dried, tightly laid, and adequately supported plank decking, tongue-and-grooved or splined, is very satisfactory for the average case.

Discussion of other details, such as *windows, doors, columns, stairways, elevators*, etc., is beyond the scope of this article.

Special Provision for Unusual Equipment or Processes. In connection with building design and arrangement, it is well to provide for such items as: special machinery foundations, moisture proofing of floors or walls, adequate aisles, doors, elevators, etc., for the largest and heaviest machinery or product, conveyers, cranes, and other such facilities, and particularly underground services or elements involving building changes if installed after the initial construction. Where electric trucks are to be used, nine-foot width for main and five-foot for branch factory aisles is ample. In general main doorways eight feet wide by eight feet high are satisfactory. Where special processes involve splashing of water, oil, or chemicals, (e.g., electroplating) considerable difficulty and expense in subsequent maintenance can be avoided by providing at the outset an impervious floor, which will be unaffected by the conditions to be met. A general-purpose building, of usual design and construction, is not likely to be suitable for all sorts of operations without some modifications, many of which are best made during the original construction.

Building Accessories and Special Features.

1. Heating, ventilating and conditioning.
2. Power, electric and steam.
3. Illumination.
4. Sanitation and waste removal.
5. Fire prevention and protection.
6. Water supply.
7. Offices, warehouses, and other special buildings.

1. Heating, ventilating and conditioning means:

Proper quantity of air to be supplied, distributed, and discharged.

Proper temperature and humidity to be maintained.

Proper quality of air to be assured—reasonably free from dust, odors, bacteria, etc.

These are increasingly realized to be important, both for health of employees and quality and uniformity of product. The most desirable temperature, humidity, and rapidity of air change varies with types of work and workers (active or inactive, men or women) but for any given department uniform conditions are desirable. Temperatures should be regulated at the working plane (say three to five feet above the floor); cold drafts along the floor should be avoided. In general, 65° to 68°F. with 50 to 60 per cent relative humidity is desirable; with lower humidity, a higher temperature is necessary for comfort.

Heating systems most commonly used are:

a. Direct: radiators, pile coils, etc., exposed on building walls or ceilings. Such a system is low in first cost, involves no power and little maintenance expense, but is ineffective for large areas due to poor heat distribution and contributes nothing to adequate ventilation. If the radiators are installed

on the walls below the windows, they take up valuable wall space, and are often blanketed by machinery, benches, bins, etc., so as to greatly reduce the heat emission. If the radiators are put overhead, there is no tendency for heat to reach the working plane near the floor, with the result that the ceiling must be overheated to secure comfortable temperatures below.

b. Indirect: central heaters with duct distribution to the working areas. This method is much higher in first cost and requires power and maintenance for blowers and motors; but gives excellent heat distribution if properly designed and can also furnish adequate ventilation and conditioning. In reinforced concrete buildings, the columns and beams or pan-construction floors can be made hollow to serve as distributing ducts. Exposed sheet metal ducts are bulky and often interfere with overhead shafting, etc. Alterations to such a system are not easy.

c. Unit heaters: small heating units and fans distributed throughout the area have increased rapidly in popularity. They are moderate in first cost, reasonably low in maintenance and power expense, flexible for operation and rearrangement. Such heaters can be located overhead, out of the way, and yet direct the warm air to the working plane, including the necessary provision for fresh air supply. These unit heaters are usually extremely compact and light.

Ventilation is particularly necessary where fumes, dust, or vitiated air are prevalent; minimum requirements are often prescribed by state labor codes. In general, thirty to fifty cubic feet of fresh air per minute per person is desirable. Some change of air can be expected due to opening and closing of doors, operation of elevators, etc.; the remainder should be secured by natural means such as windows, ducts, and stacks, or mechanical means such as fans for supply or exhaust.

Conditioning of air more or less closely controlled, is required for process reasons in many industries, such as textiles, food stuffs, woodworking, and paper. The necessary equipment has been developed to a high order of precision and applicability. Each problem merits individual study by specialists. Aside from the needs of a particular industry, some humidification of air is desirable from the standpoint of employees' comfort and effectiveness.

2. *Power (electric and steam)* includes such items as compressed air, refrigeration, and water (for which see 6, below) besides steam, electricity, and mechanical transmission equipment.

The first question confronting the plant management is whether to purchase or generate power. The general trend is away from isolated electric plants, and even from steam plants where, as in some large cities, it can be bought from a public utility. Reliability of service requires skilled supervision, adequate maintenance and repairs, and reserve equipment; all of these items and the capital investment for normal needs cost more in a small isolated plant than in a large central station. In some industries it is possible to schedule electrical loads largely during off-peak periods of the utility company, as in the case of electric furnace operation or water heating at night, with consequent low rates. On the other hand paper, textile, laundry, chemical, and other such plants, with the opportunity to use for process purposes

exhaust steam or condensate from the power plant, can often justify their own power generative equipment. The basis for a sound decision is a careful heat balance study, leading to true estimates of generated power costs, compared with a definite contract for purchased power submitted by the utility company, in which all factors are evaluated, such as coal, power factor, and demand clauses, and ownership of transformer and switching equipment.

If electric power is to be purchased, and no imperative need exists for high pressure steam, it may be desirable to install low pressure (say fifteen pounds per square inch) boilers, to reduce initial cost, to eliminate the need of accessories and safeguards prescribed by many state laws for high pressure boilers, and to avoid the need of specially licensed engineers and firemen similarly required by law.

If air compressors, refrigeration equipment, water pumps, or other such machines are needed, there is an opportunity to use either high pressure steam, electrical energy, or both, installing and operating that combination which gives the most economical results—perhaps steam engines or turbines in winter, using the exhaust steam for process or heating services, and electric motors in summer. A demand clause in the electric power contract, however, makes seasonal variations in load uneconomical, at least in cost of purchased energy.

Refrigeration systems are being used increasingly in connection with air conditioning equipment, besides the direct process needs for food products.

Water supply is discussed below.

The discussion of power plants is beyond the limitations of this chapter. Among the elements with which the management may be concerned are: disposal of ashes; control of cinders and smoke, possibly regulated by local ordinances; selection of economical sizes of units, with provision for future expansion; storage of reserve fuel; proper cost distribution to plant departments; and periodic analysis of total and unit costs.

3. *Illumination* is an important item from the standpoint of quality and quantity of production, and freedom of employees from eye strain. Adequate lighting has been proved to increase production as much as 25 per cent in some cases, and to reduce waste, spoilage, seconds, and other such losses even more. Proper design of a lighting system involves consideration of:

Intensity (quantity).

Color.

Distribution (evenness).

Diffusion (absence of glare).

Steadiness or uniformity.

The desirable intensities and types of lighting units for various sorts of work are available in reference books. In general, modern practice uses higher lighting intensities than was common a few years ago, say five to ten foot-candles for average work. The trend is also toward fewer and larger units. Many state labor codes prescribe certain lighting features, such as keeping the source of light out of the line of vision by proper reflectors and mounting heights. Light colors, such as white, cream or gray, are desirable for walls,

ceiling, exposed steel work, and even machinery or benches, as an aid to good lighting. A flat or eggshell finish is desirable to avoid glare. Incidentally, such an interior surface raises morale and promotes cleanliness. It is desirable to locate the lighting control switches centrally, controlling rows of lights parallel to the windows; the foreman, or some designated supervisor, can save considerable lighting cost by controlling lights as needed; individual workmen will seldom bother to do so. If the factory areas are not regularly used at night, a few small lights on a separate circuit should be provided for the use of the watchmen. Regular cleaning of reflectors and replacement of lamps as they become blackened is important; as much as 50 per cent of the normal lighting intensity may be lost by not doing this.

With natural lighting through plain glass, the intensity drops rapidly with increasing distance from the windows; to reach effectively the interior floor areas, the light must be diffused by ribbed or prismatic glass used for the upper window panes, with clear glass up to say five feet above the floor. The diffusing glass should be chosen and set so as to be cleaned easily, preferably with the irregularities outside and the cleaning partly done by rain. North light is most free from glare and most uniform regardless of the season or weather, since most of the natural light comes from sky or cloud reflection. Saw-tooth windows give good light if well designed and cleaned, but are not superior to monitor construction, all things considered.

Shafting, countershafting, belting, etc., interferes with good interior lighting. In making factory layouts, bench operations like assembly, inspection, and other fine work should be located in the best light, preferably near the windows. On the other hand, operations requiring absolutely uniform light and color, such as inspection of textiles, may require 100 per cent artificial light.

4. *Sanitation* includes provision of necessary toilet facilities and disposal of sanitary and process wastes. Many state labor codes prescribe in detail the number, location and restrictions of sanitary facilities, even including special washing facilities for employees handling poisonous materials. These regulations may include such items as drinking cups, towels, and soap. It is important to provide in the initial plans and construction, space and sewer connections for the maximum number of fixtures expected to be required in both men's and women's toilet rooms; only a part of the equipment may be installed initially, but expensive later alterations will be avoided thereby.

For effluent disposal, both process and sanitary, the public authorities should be consulted if a sewer connection to the public system is desired. There are usually restrictions against hazardous, corrosive, odorous, or abnormally hot or cold matter, unless properly diluted or treated. Special provision may be required to prevent stoppage or facilitate cleaning of plant sewers. In many cases, storm water and sanitary or process sewage must be handled through separate sewer systems. The protection of streams from pollution by industrial waste is receiving more and more attention, and the subject merits careful investigation by plant authorities to avoid later embarrassments.

It is a great advantage in many plants to have on the property or near-by, low ground for disposal of solid waste such as cinders, foundry slag, and other

solid waste. If such ground is to be used later for factory buildings, the filling should be done carefully to avoid excessive settling. Combustible solid refuse, such as waste paper and wood, may be burned in incinerators or, if the quantity is sufficient, under special boilers. Some plants generate an appreciable portion of their steam requirements from waste fuel. Refuse handling should be done, in general, with minimum transfer between containers, i.e., the material should be accumulated in the same trucks, trailers, cans, or boxes in which it is taken to the point of final disposition. Each item of industrial waste material should be scrutinized for possible salvage.

5. *Fire prevention and protection* is naturally coupled on an operating basis with safety, maintenance, and police functions, also with the activities of a plant inspection committee if this exists. Much good advice is obtainable from fire insurance organizations, particularly those specializing in industrial risks. Insurance rates can be lowered considerably by proper design, construction, and housekeeping; sufficiently to warrant a good deal of attention and expense in large organizations. Even with good plant construction, materials and accessories often involve enough combustible matter to be dangerous, e.g., paper and perhaps furniture in offices; wood, cardboard, etc., in packing and shipping rooms; paints, oils, and finishes in various departments. Wherever possible, the bulk of such commodities should be stored outside the factory buildings; likewise finished or semifinished parts of inflammable character.

It is not practicable entirely to avoid combustible construction, but rigorous insistence on good standards of order and accessibility to the fire fighters, with provision of adequate sprinkler and extinguisher equipment, and sufficient training of employees to cope with emergencies will usually prevent major disasters. Preventing rather than stopping fires is the desirable course.

Some one person in a small plant, or a fire chief and organized brigade in a large plant, should make regular inspections of the factory, particularly of protective equipment, and submit written reports and recommendations to the management. The fire brigade should have regular drills at stated times, with at least occasional practice in extinguishing actual fires, such as in yard rubbish. Extinguishers, hose, and fire-alarm system should be tested periodically, with written and signed records kept of conditions found. A definite report on a prepared form should cover each actual fire, the essential features besides the description of the fire itself being: probable cause, preventive action subsequently taken, and further safeguards recommended. Preventive measures, based on actual trouble, and adequately covering each particular case, will gradually eliminate likelihood of trouble. Cooperation with local public fire departments is very desirable, perhaps to the extent of inviting occasional inspection and advice, certainly assuring interchangeability of connections for hose and hydrants, although most large plants prefer to handle with their own organizations any ordinary fire.

One very important point is salvage of machinery, stock, etc., after a fire, to prevent delays in production and get operations quickly back to normal. Tarpaulins, sawdust to soak up water, and other such items should be part of the equipment of the fire brigade or salvage corps. Fire drills for the

factory employees should include definite assignments of individuals to close windows and doors, protect important equipment or material, establish fire lines and keep order.

6. *Water supply* may be public or private; the usual industrial requirements besides process needs are for power plant, fire protection, drinking and washing. A supply from the public system has the advantages as a rule of assured and consistent quality, reasonable pressure without pumping, and elimination of duplicate piping systems by using the one service for all needs. For ordinary plants, with moderate use of water, a public supply should be the most economical and satisfactory. Inquiry should be made, however, as to reliability and quality of such water. Private water systems may come from rivers or lakes, wells, or perhaps sea water for certain cooling purposes, as for condensers. Pumping and filtering equipment, with storage reservoirs in case of intermittent use, are usually necessary. Certain processes, such as those for paper, textiles, and food-stuffs, require water within definite limits of quality; sulphur, dissolved salts, acidity, or alkalinity are important. Water for steam boilers is subject to similar limitations; as a rule artesian well water is not suitable for boiler supply, while it may be admirable for making beverages or other process purposes. Drinking water must, of course, be reasonably pure from a bacteriological, as well as chemical, standpoint; the state boards of health and other public authorities enforce rigorous standards and test such water. In some cases the need of refrigerating drinking water in summer can be avoided by permitting a slight flow at the drinking fountains or from the end of the main. In general it is not permissible to connect public and private water systems, or raw water mains with those for drinking water, without thorough safeguards against back flow into the purer system; even the best of such safeguards are none too satisfactory.

For fire protection, sprinkler systems, hydrants, fire-pump supply, etc., the water supply must be adequate and reliable. A reservoir or gravity tank is usually required, with piping arranged as a loop, grid, or multiple feed. The criterion of adequate pressure is sufficient supply to the highest floor of the building. Underground water piping should be buried deeper than the frost line, minimum depth varying with the locality; such piping is expensive to change and should be installed amply large at the outset, with due regard to possible future plant development, that is the depth should depend on grading or excavation expected.

7. *Special buildings* such as offices and warehouses deserve a few general comments. *Offices* should be centrally located, with convenient access from the street for visitors without passing through factory areas. A separate building is usually desirable, except in small plants, to protect office work against noise, vibration, fumes, etc., from the plant, and keep office people from too much contact with the shop. On the other hand, production and engineering records, blueprints, order information, and the like should be conveniently accessible from the plant, to avoid the need or excuse to build up duplicate files and do extra paper work in the shop.

Warehouses for raw material and finished product, separated from manufacturing buildings, are desirable in large plants, for safe and convenient storage and shipping of product; such arrangements are, of course, particu-

larly necessary where the business is seasonal, requires lot manufacturing for stock, or involves a large number of raw or finished items. Lower insurance rates on material stored may be expected on this basis. The warehouses should be arranged for minimum movement of material, and easy inventory and selection of items; raw material can be carried in lots convenient for plant use, perhaps in tote boxes or on truck skids; finished product can be stored in shipping containers. It may be possible to use conveyers to and from the warehouse and cars or shop. Large warehouses should be divided by fire walls, with about 5,000 square feet per section.

Shipping and receiving areas may be housed with the manufacturing space or the warehouse. Among the desirabilities are: space and facilities for checking consignments, perhaps for inspection, or for holding a particular lot while a few samples are investigated; protection against pilfering; sufficient space and facilities to load or unload cars without demurrage; perhaps parcels post, express, truck, boat, or other transportation facilities. Analysis of the character and volume of material handled will usually indicate the applicability of some labor-saving appliances, such as overhead hoists or cranes, conveyers, hand or electric trucks, special scales, wrapping machinery, or the like.

Construction and Installation. Except on minor projects, or where a sustained construction program justifies a standing organization for the purpose, it is not usually desirable to attempt *design and erection of factory buildings* within the industrial concern's personnel. Such work, particularly construction, requires a force of men not normally usable during plant operation. The interrelations of the building trades are complicated and often difficult to handle and the situation is affected by labor union conditions which are particularly strong in the building trades. It is rarely practicable to develop rapidly the necessary working and supervisory force, tools, etc., within the plant, and to disband them at the end of the job. Consequently industrial construction work is usually handled by outside architects, engineers, and/or contractors.

On the other hand, *installation of machinery and equipment* is often handled to better advantage under the supervision of the plant engineer or master mechanic by his own men, perhaps including branch piping and wiring, benches, material-handling equipment, and the like. It is sound practice to have the initial installation of machinery made wherever possible by the men who have to keep it going; maintenance work is likely to be reduced thereby.

An excellent arrangement is to have the outside architect or engineer provide for supervision of the construction work from the owner's standpoint, by means of a resident engineer, and let the individual contracts, thus eliminating a general contractor's profit. However, for extreme speed, or with a very large number of separate subcontracts to be interrelated, a general contract on a bonus and penalty basis may be preferable. The normal duties of a resident engineer are to:

- Coordinate various contractors.
- Interpret plans to these contractors.
- Supervise construction operations.

Expedite work and develop schedules.
Approve work and turn it over to owner.

Such duties may be handled by the plant engineer, if his other responsibilities permit.

An important element is scheduling of the construction, as a means of planning the job itself, and to inform the owners when a part, or the whole, can be turned over to manufacturing. Weekly progress reports are desirable, showing per cent completion of each item on the master schedule; each major item of work should be plotted separately, including necessary material. In many ways, the hardest part of a construction job is the final clean-up, removing surplus material, tools, etc., and bringing the work from 99 to 100 per cent complete. This stage of the job includes checking and acceptance, so that both owner and contractor have a clean cut knowledge of the time when responsibility is transferred.

When additions or changes to an existing plant are to be made, with the minimum interruption to manufacturing operations, a definite understanding should be reached as to areas open to contractors, use of shop facilities such as power, sanitary, and tools, handling and storage of material, including use of railroad sidings, and general plant regulations such as smoking. In many cases it is desirable to fence off the construction area from the operating area, using a separate entrance.

The desirable basis of any *construction contract* is one that is fair to both sides, owner and contractor. If the contractor finds himself working at a loss, there is too much temptation to save money by slighting the work. The trend is toward standard forms of contracts for various elements of the work, with the advantage of uniformity, elimination of "trick" clauses, etc.; these are sponsored by American Institute of Architects and various trade organizations such as steel and concrete. There are several forms of construction contracts, each suitable for certain conditions.¹

A considerable saving in construction cost is possible by wise selection of the *proper time*. Within recent years there have been wide fluctuations in supply and demand of labor and material. Winter or off-season building is being encouraged by improved construction methods and often shows a saving. While a large job is underway, minor or supplementary work can be done economically by the use of contractors' organization and equipment.

CHAPTER IV

PLANT LAYOUT

BY CHARLES H. HATCH, *Vice President, Miller, Franklin and Company, Inc.*

It is safe to say that at least 75 per cent of all plant layout work is primarily a problem in cutting the suit to fit the cloth. Occasionally, of course, the engineer is allowed to proceed unhampered—even to the extent of designing the building to suit the ideal layout. But usually his problem is to work out a new layout of machines and equipment for an existing plant. Even with a new building there usually are hampering conditions determined by the shape of the lot, the location of transportation facilities and so on. Thus it is frequently necessary to work out the best practical layout for a four story plant when the ideal condition would be to build that particular product in a single story plant, or *vice versa*.

But even so it is usually possible to devise highly efficient layouts despite such obstacles, provided the engineer has a clear-cut conception of the types of production and of certain fundamentals that underlie all production.

In this chapter we are treating the majority of cases where there are hampering obstacles. Once the engineer understands how to plan layouts under these circumstances, he will find no difficulty in laying out a new plant with no restrictions, should he ever be fortunate enough to encounter such a case.

The fundamental principles of plant layout as they are described in this chapter apply to a greater or less extent no matter whether the plant is in the field of metal working, woodworking or what not. Because metal working shops present all of the problems and complications that are to be found anywhere we have taken our illustrations from metal working in this chapter. But the principles apply to shops turning out any kind of product.

Layout Depends on Type of Production. We have seen in Chapter I that production in which machines are used is of three fundamentally different types. They are: *mass production*, where large quantities of a single or at most a very few varieties of goods are produced by repetitive means; *job production*, in which no jobs may be exactly alike and long runs on a single product are unknown; and *job mass production*, under which a plant or part of a plant may run for a comparatively short time on a single product, simulating mass methods but which must at intervals change over to some other product usually similar in nature which is again turned out for a while.

Because of changes in style of product and the desire to diversify a company's "line," the majority of factories come under the category of job mass

production. There are practically unlimited graduations from the plant which closely resembles mass production to the one at the other extreme which partakes mostly of the strictly job shop. The plant layout will naturally reflect the nature of the production, provided, of course, that the engineer who designs the layout is competent and realizes the nature and peculiarities of the problem.

Functionalized Departments. In pure *job production* strictly functionalized departments are the rule. That is to say, taking a machine shop as an example, there will be a department containing no productive machines other than drill presses, another given over entirely to lathes of various sizes and designs, all planers will be in another group, there will be a department that does nothing but grinding work and so on. Because of the fact that the output will be highly varied in nature various sequences of operations will be required and therefore a certain amount of back tracking will be inevitable. Consequently the location of departments is not of such surpassing importance as in the plant which will operate on a mass, or modified mass, basis. The principal thing is to make certain that ample provision is made for trucking aisles and storage space in the departments, for goods in process. It is, however, easy to avoid such ridiculous errors in laying out a job shop as placing the grinding operation which is always one of the later operations next to the raw material stockroom.

Even in job production it is often wise to separate heavy duty and light duty equipment of the same kind into two separate departments and to locate them properly so as to reduce hauling and trucking.

Under job production it is also sometimes wise to separate roughing equipment from finishing equipment in a department or if the shop is large enough to make separate roughing and finishing departments. The class of labor and the tolerances in the latter instances are different.

Multiunit Plan. In *mass production* most of the departments will be laid out on the line or, as it is often called, the multiunit plan. That is to say several machines of different types will be arranged to perform in proper sequence the various operations required on a particular part of the product. Thus a single production unit may comprise a multiple drill press, three planers, two milling machines and four grinders, each performing its particular operation in its proper order. The unit would work on its product and nothing else. The proper grouping of the various units would comprise the line of production, that is, the assembling and correlating of unit productions. Several groups may pour their product into the main line at various points. A group may in some cases be a department in itself.

While we have mentioned specifically machines which can be used on various products it is often the best practice in a line department to use special purpose machines. This phase of the problem is, however, discussed in detail in Chapter V, Machinery and Equipment.

Combined Functional and Line Departments. In a plant which is to operate under what we have called job mass production it may be advisable to have both functional and line departments although in certain cases which closely approximate pure mass production it may be possible to set up nothing but line departments.

Suppose a plant were to make nothing but rear axles for automobiles, that the basic design of all these axles would be the same, but that minor variations were necessary to meet the needs of the various customers. In such a plant it probably would be possible to lay out the plant with nothing but line departments making necessary changes in tooling when production was changed from one type of axle to another.

On the other hand consider the problem that was presented in designing the layout of a plant which was to produce electric refrigerators. It was known that from time to time there would be engineering changes in the refrigerators which would naturally affect the operation to be performed, while other parts of the product, it seemed likely, would be unaffected. The parts subject to change were therefore made on practically a job basis in functional departments while for those parts unlikely to be changed line departments were set up. The assembly department was also laid out on a line basis because the changes would not affect the assembly as a mass operation.

Breaking Down a Functionalized Department. In a plant that operates on the job mass production basis it is often desirable to break down what would normally be a functionalized department into links in two or more line production groups.

Thus in one plant there were four different parts entering into entirely different subassemblies that had to be tinned. Since tinning is a process that requires a certain degree of skill especially in supervision, the usual practice was to have a central tinning department through which all parts to be tinned passed. There were certain obvious advantages to this plan, but there were also certain apparent disadvantages, chief of which was the necessity of breaking into what were practically line set-ups designed for mass production in order to haul the parts to the tinning departments and back.

Analysis of the problem, with special attention to the relative costs of equipment, trucking and delays to production, showed that it would pay to divide the tinning between the four departments and maintain a smooth flow along mass production lines. The equipment for four separate tinning sections cost more than the equipment for a central department of equal capacity, but the saving in trucking and lost time more than made up for the increased investment.

The foreman of the old tinning department was given supervision of the four tinning units under the foremen of the various departments.

Dealing with Heavy or Bulky Parts. When analyzing the product to determine whether it shall be made by mass, job or job mass methods it is also essential to consider the weight and the bulk of the various parts. It is evident that it is much more expensive to move a bulky or heavy part than a light, small one, especially if the movement is up and down.

In designing a plant layout great economies are realized when the heavy and bulky parts, like sediment, stay at the bottom. Therefore in a multi-story factory the capable engineer will resort to many ingenious expedients in order to keep all of the processing of heavy parts on the ground floor, where they are usually received and from which they are shipped.

There is another advantage to this aside from the saving in handling cost. Operations on heavy parts are usually performed on heavy machines. On the ground floor it is possible to secure ample foundations for heavy machines at much less cost than would be entailed on upper floors.

In processing plants such as chemical industries it is not always possible to avoid elevating heavy materials. The equipment itself must sometimes be two or more stories high and the materials fed in at the top, passing through the process by gravity. This is one of the cases where the nature of the equipment determines the layout—not at all a universal condition.

Flow of Materials. When it is known which parts should be processed on the ground floor and which can properly be raised and lowered at a not excessive cost the next point to determine is the flow of materials.

A common mistake is to postpone that until, either by cut-and-try or by wholly arbitrary means, a more or less tentative layout of the departments has been fixed. I am convinced that that is putting the cart before the horse, and that the proper starting point is to lay out the channels through which the materials will move. Despite the fact that it is often said to be impossible, I know from experience that it can be done and that the final definite plant layout will be far more effective.

While it might be highly desirable to take raw materials into the plant at one end and route the product straight through to the finished stock room and shipping platform at the opposite end, that may be out of the question due to the fact that the only available space for the railroad spur is at one side of the plant. In that event, if all receipts and shipments are made by rail, it will be necessary to bring the material in and take the finished product out at the same side of the factory. Therefore the line of flow cannot be in the ideal straight line but must be designed as a circulating system.

Traffic Lanes. It is to be remembered that in any plant there is not only a primary flow of materials through the factory but secondary movements as well. Once the general, primary flow of materials through the plant has been determined, the next thing is to lay out the general traffic lanes. These should, where possible, be in a straight line.

The traffic lanes may be laid out on floor plans. But a better method, because it aids in visualizing the layout, especially if the factory has more than one story, is to build a dummy floor plan of the plant on which the traffic lanes and the actual equipment, productive and non-productive, can be shown to scale. This is particularly valuable in securing the advice and suggestions of the foremen, who frequently have worthwhile practical ideas. The average foreman may have difficulty in visualizing a layout from process charts but he can easily do so from a dummy floor plan.

Let us take as a typical problem a certain factory three stories high, with a total floor area of fifteen acres. The first step was to lay down the traffic aisles for the primary material flow as closely as possible to the center of the buildings. These were laid out before any of the productive departments were located, although the raw material and finished goods storerooms had been located.

These initial lines are almost certain to be changed here and there before the final layout is determined, but it is important to resist those changes to

the utmost lest the whole layout become a twisted maze of back tracking and crossing lanes which would make efficient moving of materials impossible. Before a change in the original layout of primary traffic lanes is permitted it pays to make the change justify itself beyond any possible doubt. In the example it was necessary to move one lane from the center of the building to a point about one-third of the width of the building from one side. Another was moved nearly to the wall, and certain other minor changes were allowed, yet when the final layout was established, the basic plan was surprisingly like the original tentative layout, so far as the primary movement of the materials was concerned.

Whatever changes are allowed it is essential to remember that primary flow must be kept open regardless of what final arrangement of departments and secondary flows are determined upon. The primary flow should be emphasized constantly in all of the layout work.

It is surprising to what extent a properly laid out primary-flow plan will reduce the amount of material-moving equipment required. In one fifteen-acre plant less than 200 trucks are required as a result of scientific, well-planned layout, and automatic conveying equipment is negligible.

Layout of Departments and Storerooms. When the primary flow through the plant is determined and the choice of mass, job mass, or job methods is settled, it is possible tentatively to indicate on the plans the general location and space requirements of the various departments, as well as the storerooms for raw materials, semifinished parts, subassemblies, and finished stock.

Sometimes the areas required will not fit into the general plans and it will be necessary to do some juggling and close fitting, keeping in mind that the provisions for primary flow of materials must be maintained. If the space allowance for a department must be reduced below what seems desirable or necessary for that department great care and ingenuity is needed. If more space is available than seems necessary for a department the problem will be simple because the department is then provided with room for growth with the gradual expansion of the business.

If space is not at a premium it is wise when making the departmental layout to allow for future expansion, taking into consideration which products are likely to increase in sales and how rapidly the expansion is likely to proceed.

Use of "Banks." In mass or job mass production it is desirable to provide at strategic points banks or reservoirs of finished parts or semifinished materials on account of possible delays in production due to machine breakdowns or other emergencies. In order to provide the right amount of storage space for these banks of materials it is essential that the severity and duration of possible stoppages be determined so that provision may be made for the needed amount of material.

Generally it is desirable to provide banks large enough to supply from one to six days' requirements of capacity production. For example, take the case of a product which is die stamped. The die is an expensive one which takes about two weeks to make. It would be possible to carry on hand a duplicate die, but it is cheaper to operate with only one and safeguard production by keeping a reserve bank of three weeks production of the part. On the other

hand if a machine can be retooled completely in twenty-four hours, three days reserve of the part made on that machine will be ample.

It is to be remembered that these are not theoretical reserves but actual physical stock which is set to one side and which does not get into production unless a shutdown in production occurs. It is possible that these banks may not be depleted for months.

This fact has a very real bearing on the layout of the plant. Since there is infrequent need to draw on the reserve stocks they may be stored in dark and inaccessible parts of the plant which could not be utilized otherwise, or they may be kept in the less desirable parts of the regular stockrooms.

The relative activity of different parts and materials is taken into account when designing the layout of the various stockrooms. Provision should be made for keeping the heavier items and those that are moved most frequently where they are most accessible. Often it is desirable to keep them on truck platforms in order to minimize handling.

Layout in Relation to Supervision. It is usually undesirable to locate departments primarily from the point of view of supervision. The uninterrupted flow of material in the logical order of processing is the primary objective of good factory layout—other considerations are usually secondary. It is a great temptation sometimes to locate two or more departments together merely so that they may be readily supervised by some particularly able foreman, but unless the other departments can be so located as to allow the materials to flow readily and freely to the adjacent departments the results will not warrant the deviation from correct principles. It is often cheaper in the long run to move a foreman comparatively great distances or to employ two foremen rather than one.

Repair Benches. In many types of production it pays to make provision at certain points along the production line for repair benches. In one instance that device shortened the assembly line 15 per cent. Wherever a partial assembly could be taken off the assembly line a repair bench was located. Then if any damage occurred to an assembly while on the line it was taken out of the line, repaired at the adjoining bench and replaced upon the line. Or if the repair could not be made so easily the assembly was taken apart and the good parts sent back to the beginning of the assembly.

Shapes for Secondary Flow. With the primary flow of material and the general location of departments determined, the next step is to lay out each department, keeping in mind that travel should be as short as possible.

Usually it is desirable to take material into the department and complete it as close to the main aisles of flow as possible. Often this is done best by having the secondary flow within the department follow a U-shaped path with the horns of the U at the main aisle. In some departments the path may be almost a perfect circle, the material leaving the department at practically the exact point at which it entered.

Under certain contingencies the best result is secured by having the materials follow an S-shaped path through the department, entering from one aisle and leaving at another.

The E-shaped path is often well adapted to production needs. In some cases two parts that are to be assembled may come into the department and

be processed on the top and bottom arms of the E, travel along until they meet at the middle arm, be assembled and pass out of the department over the middle arm. Again, especially if a department contains machines of widely different capacities, it may work well to have the materials enter the department in a single stream over the middle arm of the E and leave in two streams at the top and bottom arms. Such a case would be where the first operation was performed on a machine which has twice the production of the machine which performs the following operations. In that case the first machine would be on the middle arm and would handle all of its operation on all of the parts that came to the department while the subsequent machines on the top and bottom arms would each handle only half of the production of the department.

In making the detailed inside layouts of the individual departments it is of importance to consider the necessity of keeping the moving of materials as easy and cheap as possible. If the product is light it can often be passed by one operator who has just completed his operation upon it to his neighbor who will perform the next operation. Sometimes this can be done directly from machine to machine or from bench to bench. Again it may be necessary to have an intermediate truck or rack.

Spacing between Equipment. It is to be observed in this connection that spacing between machines is deserving of more accurate determination than it ordinarily gets. In the effort to have machines close for easy handling of material it is possible to make a department too crowded for efficiency.

On the other hand it is bad to have a preconceived idea as to the desirable distance between equipment. In one plant soldering benches were arbitrarily spaced three and a half feet apart. The parts to be soldered were pieces of pipe two and one-half feet long. It had been the practice for the trucker to put a supply of pipe on each soldering bench where they were in the way of the worker. The benches were put two feet apart and equipped with stops so that the ends of the benches could be used as racks, an end of the piece resting on each adjacent bench. In this way the benches were kept freer of material and the workers could perform their operations to better advantage.

Maintenance, Service Departments, Etc. It is desirable to have maintenance and service departments either in close proximity to the departments that are to be served, or centrally located. It is unwise, however, to disarrange production departments in order to locate service departments except in special cases where continuous and heavy repairs and maintenance are required, or where accurate and delicate adjustments must be made.

Clerical service departments should if possible be centrally located. This, however is not paramount. Wherever practical, departmental offices should be centrally located in the department or as near thereto as possible.

Wash rooms, coat rooms, etc., should be ample and usually adjacent to the productive department or group of departments. Another alternative is to have general coat rooms at the plant entrance with wash rooms close to the separate departments.

Ample provision should be made for railroad sidings, receiving and shipping platforms. These are governed by various conditions peculiar to each plant. Where large quantities of materials are received and shipped it is advisable to

enclose or partially enclose the platforms for protection against the elements and to reduce the heat loss in the winter. That is quite a problem where bulk is handled.

In establishing the internal traffic system free access to stairways should be provided and roads or walks should be provided to take care of foot traffic. Runways from roads and walks for medium elevations are preferable to short flights of stairs.

In laying out a plant provision for automobile parking space should not be overlooked. It is difficult to estimate space requirements per employee for this purpose as it varies according to locality of the plant. For instance, in a plant between Bridgeport and New Haven on a bus line, 250 men are employed and the average parking is 140 cars. On the other hand in the city of New Haven, on a car line, the average parking is 22 cars for a plant employing 100 men.

The location of outside cranes, hoists, gantry cranes, etc., is also dictated by the necessity of the individual plant. The fundamental point to be remembered is that it costs money to lift material or to carry it any distance. Therefore it is economical to keep the lifting and carrying at a minimum.

Conclusion. In plant layout there are few, if any, detailed rules that can be fixed. There are, however, a few fundamentals or general rules that can be enumerated, as set forth in this chapter.

The important thing is to keep in mind constantly the peculiarities of the products to be produced, the type of manufacture that is to be used for such a product and the fact that a straight line is the shortest distance between two points.

CHAPTER V

MACHINERY AND EQUIPMENT

BY W. S. POWERS, *Field Staff Director, Miller, Franklin and Company, Inc.*

In selecting the machinery and equipment for a plant, as in designing the layout, it is essential if the best possible results are to be achieved to determine definitely and accurately at the outset just what plan of production is to be used: whether mass, job mass or job production. This involves, first, an analysis of the products into their component parts; second, a study of the present market and the probable future trends in styles and consumer preferences and, third, a determination as to whether advances in engineering are likely to change radically the product or its method of manufacture.

If the product is one that can be sold indefinitely in quantity, and if little or no change due to style changes or improvements in design is to be expected, mass production is indicated. If considerable runs can be counted on between changes modified mass production will be the plan to use. If only a single piece or a very few of each kind will be made at a time, job production only can be used.

Single-Purpose vs. Standard Machines. A few years ago the general practice was to use single-purpose machines wherever possible because of the fact that on long runs they were as a rule more efficient than multipurpose machines. Today there is a strong tendency away from single-purpose machines and toward standard machines. There are two reasons for this. One is that a highly specialized single-purpose machine is likely to become useless if radical changes are made in the product. Another is that machine builders have succeeded in building standard machines of such wide range and adaptability that they can by adjustment be applied to many special uses and perform with a high degree of efficiency—often they are as efficient producers as the single-purpose machines.

Machine tools as used in metal working are an example. In the old days a milling machine was a milling machine, a drill press was a drill press, and that was all they were. Today a standard milling machine is available which can be adjusted to mill several surfaces at one time, and multiple drill presses can be secured which may be set to drill several holes at various points and angles. When the product is changed permanently or when under job mass production a run is started on a different product such machines are quickly adjustable. In other words, fifteen or so years ago it was necessary to design a special single-purpose machine to perform operations that today can be done equally well on a standard, multipurpose machine.

This is true not only of the highly refined automotive industry but of all of the multitudinous branches of metal working, woodworking, and fabrication of various plastic substances.

In textile and clothing manufacture there are few single-purpose machines. A loom can be changed over easily from one cloth construction to another. While of course there are special machines for cutting, sewing, buttonholing, blind stitching, and the like, they are not single-purpose machines because they can be used for their particular operations regardless of the design of the clothing that is being produced.

In the many different branches of the chemical industry we find both special single-purpose equipment and standard equipment. In highly complicated processes special equipment, unfitted to any other product, must sometimes be used. This often results in a whole series of machines or even a whole plant becoming obsolete due to the discovery of a much more economical way of turning out the product. In other cases, the machinery is quite standard and can be adapted for use with a wide variety of products. A case in point is mixing machines which can often be used for mixing many different chemical products.

High Overhead on Single-purpose Machines. Even in mass production on a well established probably permanent product it is not always desirable to use a special single-purpose machine. Such a machine is often very expensive, entailing a high overhead rate for interest, taxes, obsolescence, and so on. Even though its use might result in great economies in labor when the machine is active, this saving could conceivably be eaten up in uncontrollable overhead expense if sales fell off enough to prevent full use. In other words, when production declines, workers can be laid off temporarily and their wages saved, but a machine cannot be laid off and a large part of its overhead expense goes merrily on whether it is at work or not. This is true whether we are thinking of business depressions or merely the peaks and valleys of seasonal production. The bill for wages is flexible; a considerable part of the bill for overhead on a machine is extremely inflexible.

This balance between the saving in wages and the continuing overhead expense is one that should be given consideration before deciding to spend a large sum on special machinery.

Permanence of Design of Product. The possibility of changes in design of the product must also be considered when deciding between special and standard equipment. This came out strikingly in a metal-working plant making a part which is purchased by most of the larger automobile manufacturers. Little change had been made in the product for a long while, yet there was no assurance that there would never be a change.

This part required, when made on standard machines, the time of twelve men. Investigation disclosed that a special machine that would cost around \$30,000 could be developed to turn out the same volume of production with only two men. That of course would have been a very attractive saving in wages. But that machine would have been so special that it could not be adjusted or changed to meet the requirements of even a minor change in the design of the product. If a customer demanded a slight change in dimensions of the part the entire machine would become obsolete instantly and without

warning and would have no value except as junk. Under the circumstances it was decided to pass up the saving that the special machine would have made and not run the risk of investing \$30,000 in something that might become valueless overnight.

Adopting the Latest Improvements. A very great temptation exists for the progressive production man to keep in the front of the procession by adopting the latest improvements in equipment, whether productive or non-productive, which can be proved to have cost cutting possibilities. That is an admirable frame of mind but it may turn out to be expensive. It has been well said that the sound plan is to be neither the first nor the last to adopt new inventions.

In the past few years there have been very rapid advances in the efficiency of machines. A new tool would be developed which would show an indisputable cost reduction of, for instance, 10 per cent. A fair-sized investment would be made by a manufacturer in these new tools. Then in a few months or a year this tool might be still further improved so as to increase production or decrease costs another 20 per cent. The management would decide that this saving was too attractive to pass, and would forthwith sell the older machines for what they would bring and reequip with the latest improvement. In some cases these recurring improvements happened a half dozen or so times, at an expense for obsolescence that far exceeded the operating savings realized. In one instance, within a very few years a loss of several hundred thousand dollars was built up in just that way. It was charged to obsolescence but it should have been charged to an account called "ultraprogressiveness."

It is quite the rule that when one more or less revolutionary improvement is made in a machine, others are nearly certain to follow quickly. Of course, to drag along too far behind the procession of progress may be fatal in that it may raise costs sufficiently to make it impossible to compete in the open market. To know just when to adopt cost cutting improvements calls for good judgment and it pays to study these possibilities before rushing to displace the old equipment with the new.

Basic Factors in Choosing Equipment. In considering the type of machines and tools to be used, quite competent factory executives are prone to consider only the more obvious high spots of the problem and overlook the more obscure but often decisive factors. This is true both in considering the relative desirability of special-purpose machines and standard machines, in deciding between a comparatively inexpensive machine and a better one at a higher price, and even in determining whether to use a machine at all.

It comes finally to a debate between the *desirability of using labor or machines*. To read much of the literature on industry currently written by laymen whose knowledge is likely to be far more theoretical than practical one would infer that American industrialists invariably displace a man with a machine whenever the chance exists. Admittedly there has developed a sort of religion in which the machine is God, and many factory executives are converts to the cult, but it is not the practice of leaders who test everything they do with the question: Does this render value received?

Let us view some of the considerations that bear on the use of labor as against the use of a machine. There is the flexibility already mentioned, of

labor compared with the inflexibility of the machine. This applies to all machine work as against hand work. The laborer can be transferred to other departments, the machine cannot. Again the production of most machines is set. There is not much chance to increase materially the production of a well-designed machine by the adoption of better methods, while the production of a worker using tools or simple machines is often subject to great increase. The validity of such a consideration would of course depend upon the relative production under the two plans. If there were a great initial advantage with the machine, the machine would probably be preferable if the investment were not too great, for the handicap at the start would probably be too great for the hand work to overcome through any likely increase in efficiency.

In weighing the desirability of man work as against machine work the cost of training is important. It generally costs much more to train a man to do hand work than to teach him to operate a machine. If men are laid off either on account of a protracted depression or to meet seasonal declines it may not be possible to get those same men back when business picks up and it may be necessary to train a new lot. Much of the value of the machine lies in the fact that to a large degree the skill of men has been transferred to the machine.

The relation that exists between the management and labor also has a bearing on the problem of whether to use more machines and fewer workers or *vice versa*. If there are no labor troubles it may be desirable for other reasons to use men instead of machines. But if the relationship is strained, it is often desirable to be as independent as possible of labor and so to rely to the utmost on machines, even though other considerations might point to the desirability of the other plan.

In starting to make a new product it is especially essential to *weigh carefully the efficiency of production against the cost of the equipment*—which is subject to obsolescence. When efficiency and all other considerations are equal it is always desirable to make the product with the cheapest tools possible.

Therefore it pays to examine the product in order to find out whether by slightly changing its design it may not be possible to make it on some less expensive machine. Even though the original design may meet with complete consumer acceptance it is often found possible to make changes which will not affect the acceptability while making it possible to produce at a lower cost.

It practically never is safe to start off with highly refined machinery and tools for making a new product. Let the tool design go along with or even follow the design of the product as affected by the lessons learned in marketing it. Thus even though a new product may be one that can ultimately be made safely by pure mass methods, it usually pays to make it at first with standard equipment for job mass production, or even in some cases by straight job methods, even to the extent of having proportionately more hand work than machine work.

It is necessary to be cautious in making heavy expenditures for machines, tools, and other equipment, and when improvements are finally decided upon, to make them little by little, rather than by sweeping changes. In that way the original job methods of production will be retained for a while although

when possible economies in those methods are discovered they will be adopted. These tentative economies may be the most potent factor in pointing the way to the methods which will ultimately be used when mass production is finally installed in all completeness.

What should be the attitude of the management in regard to *keeping in touch with developments in productive machinery* and other equipment? Does it pay to spend money and time looking around for improvements which might possibly arise, and would, if adopted, result in lower costs? Or is it better to sit tight and let the equipment manufacturers force their new machines upon the factory management?

To some extent this depends upon the capabilities of the production executives. If a plant is well equipped at the start it never seems to benefit from going out of the way to keep up with all the latest developments. On the other hand most of the savings originate within the plant. The production men are better acquainted with their particular processes than any equipment manufacturer can be.

The best results seem to come when the production men keep up a constant study of their own problems and, upon seeing a place where betterments can be made, go to some machine maker with their specific problem and lay before him their suggestions. The place to start betterments is where the machines are to be used.

This plan is not only effective, it is one of the most certain safeguards against making premature changes in machinery which may end in extravagant charges for obsolescence.

In arriving at a final decision as to the extent to which machines shall be used—and this includes the use of special machines as against standard machines of less productivity—it is a matter of dollars and cents evaluation of the various factors for and against both plans. *Only by taking into consideration every element which will have an effect on final profits can the best possible decision be reached.* Some of the factors are definitely known. Others such as the chances of change in design of the product or improvement in the machine involve a study of the probabilities. While they are not definitely ascertainable they can usually be determined within a reasonable degree of probability. When there is doubt it is better to be conservative and avoid risking great amounts of capital on a long chance.

Determining Number of Machines. The factors which determine the actual number of machines to be used are as follows:

1. The number of shifts to be worked.
2. The desirability of operating certain machines at more than their rated capacity.

Far too often the size of the plant and with it the number of machines to be installed at the outset is determined more by preconceived beliefs and traditions than as a result of scientific analysis and a careful balancing of all the economic facts involved. There is no doubt that most branches of American industry are suffering from considerable potential overproduction. This is due to a number of reasons, among them too many factories, too much

obsolete machinery which cannot be operated efficiently at any time and at a profit only in the rare times when production temporarily falls behind demand and prices are therefore high.

Problem of Number of Shifts. Of equal importance with any of these—although not so often mentioned—is the fact that too many factories are equipped with machinery to take care of normal or in some cases peak production with one shift operation.

It is perfectly evident from an accounting and economic viewpoint that it is desirable to keep equipment busy to the greatest extent possible. Much of the overhead expense caused by investment in machines goes on twenty-four hours a day every day in the year whether or not the machinery is turning out goods or lying idle. From a theoretical economic standpoint, therefore, it would be sensible to operate a plant two or three shifts. For a given production it is evident that to produce a given amount of goods only one-third as many productive machines would be necessary on three-shift twenty-four-a-day operation as if the plant operated only one eight-hour shift. If two shifts are operated the production could be obtained with half the machines which would be needed on a one-shift basis.

But there is more to this subject than economic theory.

It may be that the normal production for nine months of the year can be turned out with two shifts, but that in the busy season it is necessary to operate three shifts to keep up with sales. In many industries it is essential to have excess capacity to care for these seasonal peak loads.

If the business is such that inventories can be piled up in slack times and drawn upon in the busy season, it is possible to determine a plant size which can be operated at full three-shift capacity the year round. Such a plan, however, is not always practicable, due to perishability of the product, the danger of sudden style changes or financial incapacity to tie up the necessary capital in excessive off-season stocks.

Then, too, in many industries there is the difficulty of getting sufficiently skilled workers who are willing to work nights. This is perhaps especially true of the supervisory help. There is also often some difficulty in tying together the activities of the day and the night shifts. Night shifts usually produce at higher cost than day shifts for these various reasons although the average cost of both will be less than that of the day shift alone.

Nevertheless, in deciding upon how much machinery to install at the start it is important to make a complete study of the possibility of operating two or three shifts in order to get the largest production for the smallest investment in machines and equipment. Here again it is necessary to weigh a number of items carefully in order to get the best balance.

Probability of Obsolescence. In some cases the question of probable obsolescence of the machinery for any reason has an interesting bearing on the number of machines to be purchased.

Most machines are rated by the maker for a certain production. Yet frequently it is possible to increase that production as much as 50 per cent by driving the machine over its rated capacity. This will usually result in the machine wearing itself out in much less than its ordinary life. That may, however, be worthwhile if there is a reasonable danger that, through

change in the product or improvements in the machine itself, it is likely to become obsolete before it would wear out normally.

Let us suppose that to get the required production on a certain operation would require twelve machines operating at their rated capacity. It might further be assumed that the life of the machines at rated capacity is ten years, but that if operated at 50 per cent overload it is estimated that the machines would wear out in five years.

Now let us suppose that there is reason to believe either that the product or the machine would be changed to such an extent in about five years as to make the replacement of the machine desirable. It is evident that under such a combination of circumstances the sensible thing is to operate the machines at 50 per cent overload so that the machines would wear out at about the time they would become obsolescent anyway. Operating at 50 per cent overload it is evident that the needed production would be secured with eight machines rather than twelve. That, considering the high price of most productive machinery, is a worthwhile saving in investment.

Of course there may be complicating factors. Few problems are so easily solved as that. It might be that such a heavy overload as 50 per cent would result in excessive maintenance and repair charges against the machines. In most cases, a degree of overload can be determined which will give the lowest unit costs for the product, all things considered.

Choice of Material-handling Equipment. With such so-called "non-productive" equipment as that used in handling materials, there are usually a number of types among which a choice can be made. There is always a best way to do a thing but that best way is not usually so apparent on the surface as to be evident upon cursory survey.

Much overinvestment in such equipment and high-cost operation is due to what amounts to an obsession on the part of some engineer or production man. A hat manufacturer, who was proud of the progressiveness and open-mindedness of his plant superintendent, had in fact made quite a number of improvements in equipment and methods which resulted in lower costs. When the superintendent suggested connecting two adjoining buildings with a conveyor for handling a certain semifinished material the manufacturer assumed that he had studied the problem and knew what he was doing. After some \$3,000 had been invested in the conveyor it was pointed out by an outside engineer that the conveyor required the services of two men, one to load the conveyor and the other to unload it. All of the material had previously been handled between the two buildings by one dinky with a hand truck.

That is neither a condemnation of conveyors in general nor a blanket endorsement of hand trucks; it is merely a ridiculous example to show that the choice of equipment calls for common sense.

Even when one type or another of equipment for moving materials seems on the surface to be indicated, there may be deep-lying reasons for adopting some other type. Thus in one plant a study of the physical conditions showed that a conveyor costing \$12,000 could with the help of two men do the material moving which was taking four men and two motor trucks. On the face of it that was an investment that would pay well. But the lease on the

plant had only five years to run. At the end of that time a new location would have to be found and the odds were great that the conveyor would not fit the new plant. That meant that the entire investment would have to be written off in five years—at the rate of \$2,400 a year. All elements of cost considered, the expense would more than offset the saving that could be effected, so the conveyor was not purchased.

Reduce Handling of Materials to Minimum. When attacking the problem of material handling, the best possible approach is that which assumes at the outset that material handling is at best a more or less necessary evil, a process that is wholly non-productive in that it absorbs time and money that under ideal conditions would be spent on productive processing or fabrication. The less materials have to be moved the better for costs and for speed of production.

This approach will tend to eliminate expensive investments in trucks, conveyors, elevators, and other types of carriers. In fact when the problem of devising better ways to handle materials comes up in an existing plant the best starting point usually is the study of the existing plant layout in the light of the principles outlined in Chapter IV to see whether by rearranging the layout much of the material handling cannot be eliminated. There are cases where by this means the length and nature of the hauls have been so decreased as to permit all necessary handling of material to be accomplished with 75 per cent less equipment than would have been required with the old plant layout.

This is accomplished in two principal ways: *by placing departments in more logical relationship to each other which reduces the interdepartment moving, and by improved arrangement and spacing of machines within a department.* Often in a functionalized department it is possible to use the "pass-along" system by which each worker when he has finished his operation passes the piece to the man at his very elbow, who is to perform the next operation. Although this cannot always be achieved, it is a goal for the engineer to keep in mind if he would keep the investment in material handling equipment at the irreducible minimum.

Material-handling problems can be generally grouped according to the following classes:

1. The handling of materials in bulk, such as coal, sand, cement and the like.
2. Movement between departments when the sequence is always the same.
3. Movement between departments when the sequence varies.
4. Movement through an assembly department.
5. Movement within a department.

A great many varieties of devices have been developed to handle these different problems. Among the more commonly used are: belt conveyors, gravity conveyors, roller gravity conveyors, monorail conveyors, wood apron conveyors, slat conveyors, travelling and locomotive cranes, barrel conveyors, pneumatic pipe lines for dry, granular materials, pump pipe lines for liquid materials, package elevators, monorail hoists, lifting magnets, tiering machines, tote boxes, tractor trucks, hand trucks—two-, three- or four-wheel

lift or non-lift—industrial railroads, trailers, power lift trucks, monorail trolleys, truck platforms, and assembly conveyors.

It is to be remembered that the object is not merely to transport materials from one place to another. The aim should be rather to move them as short distances as possible, as quickly as possible, in exactly the right quantities, and in such a way as to impede the efforts of the productive workers as little as possible—all of this at the lowest possible cost. It should perhaps be emphasized again at this point that the relative costs and savings should be accurately balanced. In other words it is possible but not sensible to spend more money on refinements in material handling to achieve theoretical perfection than will be saved in productive effort.

Moving Materials between Operations. A few years ago it was not unusual for a worker at a machine to put the piece on which he had just completed his operation, beside him on the floor. When a sufficient quantity of these pieces had accumulated a hand truck would come along and the trucker would laboriously pick up the work piece by piece from the floor, place them on his truck, and haul the load to the next department where he would put the parts on the floor alongside another machine. The machine operator then had to bend down for each piece as needed and when finished replace it on the floor, and the entire laborious time- and money-consuming proceeding would be repeated many times before the part was completed.

Today it is rare to see such an inefficient method in use. Where it is necessary to use either hand trucks or power trucks, the most usual plan is to use the lift type. The materials if small and light are kept in tote boxes which rest on skids or platforms. If possible these are at a height which demands as little reaching and bending by the productive operator as possible, and no direct handling by the trucker. The truck is merely run under the platform, raised and the load whisked away. Instead of tote boxes it is often desirable to have specially designed platforms equipped with racks for the protection or easier handling of the parts.

Moving materials between operations in this way has an advantage in some cases over moving them by conveyor, in that just the right number of parts arrive at the operator's machine at the right time, with no danger of dumping too much on him and perhaps causing a congestion in the department. If the operation is a simple one which can be completed in a few seconds, a properly designed conveyor may be a real aid in speeding his output. If he takes unfinished parts from a truck and puts finished ones back, the productive operator must necessarily give some of his attention to that non-productive performance. A well-designed conveyor will, however, deliver the part to him at just the right place every time so that he can reach for a new part or return the finished one without a glance at the conveyor or a thought about the action. This results in a considerable speeding up of production—as much as 20 per cent at times, frequently 5 to 10 per cent.

In some instances it is desirable to give thought to designing what might be called a "closed circuit" conveyor, on which the part remains until the operator is ready to remove it. This in effect builds a goods-in-process reservoir right on the conveyor. The plan has wide application in a number of different industries.

Conveyors for Assembly Work. The use of conveyors on assembly work depends largely upon the size and complication of the product and on the amount of material required in making the assembly. The moving assembly line is of use chiefly when the assembly is so large that once on the conveyor it is left there. With such a product the assembly moves progressively to the various assembly points and the parts applied at those points. This may be done either by having operators at each station adding the part to the assembly, or by having assemblers move with the assembly and pick up the parts as he and the assembly pass along the line. When the production is very large it usually pays to have the work come to the man. Each man by doing the same job repeatedly becomes highly proficient.

If the assembly is small enough and light enough to be easily handled, it is usually preferable to have each assembler lift the piece from the conveyor and work on it on a bench with a suitable fixture, rather than to have him do his assembly work while the assembly is moving on a conveyor.

If progressive assembly is being done on light parts and if most of it is bench work it is usually desirable to pass the work from bench to bench by hand thus doing away with all mechanical handling devices.

It is well to remember that in assembly work the purpose of using a conveyor is to split the operations to get proficiency on the part of the workman and to make the material accessible by scattering it.

The equipment required in the *tool and maintenance departments* depends on the type of product being manufactured. Usually the work requires a considerable degree of accuracy, so that until recently the machine tools tended to be lighter than those used in regular production. As plants became larger there was more work for the tool and maintenance departments and tools were developed which gave greater production without loss of accuracy. This results in greater economy in the production of tools provided there is enough of the kind of work to keep the machine tools busy.

Most of the industrial states now have laws providing minimum requirements in regard to *safety appliances*. It is generally wise to install any proved devices which tend to reduce the possibility of accidents, not merely for humanitarian purposes, but for dollars and cents economy. It is usually less expensive to spend money for safety devices than to pay for accidents, and when a worker knows that he is working on a machine on which it is practically impossible for him to be hurt, his production tends to increase automatically.

Power Lines. It is usually advisable when building a new plant to provide facilities for electric power, steam, gas, water and air as part of the building itself since that is cheaper than to install lines after the building is erected. Therefore in the original design it is well to provide outlets at frequent intervals so that they may be tapped without installing secondary lines.

It is common practice to differentiate the various pipes and conduits by a code of colors to simplify their identification.

While in most well-designed factories there is little need to provide for mobility of the productive equipment, there are certain types of factory in which this is desirable. In that event it may be well to have a comprehensive network of power mains all over the plant with plug-in receptacles at close

intervals. One large book bindery which has many jobs running into the millions of volumes finds that it is often desirable to rearrange its equipment in order to take care of these large jobs according to mass production methods. It has its equipment mounted on casters so that it can be readily moved. Each machine has its own individual motor drive and is equipped with a length of power cable and a plug. The power mains are overhead and have outlets at such close intervals that no matter where in the plant a machine may be placed it is within plugging distance of the power.

It is, however, rare that such extreme mobility and flexibility are required. For the ordinary plant such provisions would doubtless cost more than they would be worth.

The nature of the production determines whether group or individual drive is best. If a group of machines is of such a nature that when one of the machines is in use the other machines in the group are likely to be also, the group drive is cheaper. If, however, it may frequently be necessary to operate one machine but not the others the unit drive will be cheaper.

If steam is necessary for other purposes than heating the buildings in cold weather, the layout of steam lines and the method of generating the steam are worthy of careful consideration. If the plant has its own power plant it is usually best for economy in generation to generate all steam for whatever purpose in the central boiler room. When a small amount of process steam is needed at a point far remote from the boiler room, it would probably be less expensive to put a small boiler close to the point where that steam will be used than to run a long pipe line to the point from the central point.

The same considerations are involved if power is purchased. If a large amount of steam is required at a few points reasonably close together the central boiler is usually cheapest in the long run, but if only a comparatively small amount is needed at widely separated points it is usually cheaper to have smaller heaters right at the point where the steam will be used.

Communication methods for factories have been highly developed. In small factories it is generally satisfactory to secure interplant connections through the private branch telephone exchange which is connected with the outside through the company switchboard. If the plant is fairly large or if there is a tendency for employees to use the outside wires excessively for private calls, it usually pays to have a plant switchboard in addition to that giving connections with the outside.

In a plant having more than 20,000 square feet of floor area it will pay to have some modern type of call system.

In some factories it is also desirable to have some system by which written messages may be transmitted. For this purpose the telautograph or even the electric typewriter may be desirable. If, however, the actual original message in the form of a memorandum or a filled-in form must be delivered it is well to consider carefully the advantages and disadvantages of messengers, basket conveyors, and pneumatic tubes. The pneumatic tube system is chiefly in use where a great many papers must travel between certain definite points and where great speed is essential.

The various types of *time recorders* range from hand stamps to centrally controlled electric stamps. The electric type is of value in large plants where several time-recording stations are required, in that they are more accurate and more easily maintained. In a small plant the hand stamp or the use of the clock and the written time is usually sufficient and more economical.

For in-and-out time recording the electric stamp is universally used. In-and-out clocks may be all concentrated at the entrance to the plant or scattered throughout the plant in the various departments in which the operators work. Concentration at one point allows of closer supervision of the men during the time they are entering and leaving the plant. Locating the clocks in the department has the advantage of showing the time at which the men arrive at their departments rather than at the gate of the plant and also does away with the congestion which is liable to develop at the central point.

In many plants that locate clocks at the gate the men are required to enter the plant at a certain specified time before the work starts in order to insure that they may be at their departments.

It is possible in the small plant to combine the use of the departmental clock which is used to designate the time taken on the various jobs with the in-and-out function of an in-and-out clock.

Dies, Jigs, and Patterns. Since dies, jigs, and patterns usually are expensive, precautions should be taken to insure that none are made up unless they are necessary. The relative advantages of various types of dies of different original cost should be weighed against the possible saving, special consideration being given to the number of parts which are to be made. There is also the question of using jigs and fixtures at all. Here again it is a matter of balancing the cost of the tool against labor cost. Not to use a jig may cost more in labor than the jig would cost, and *vice versa*. On many operations a jig or die may be absolutely essential for accuracy. Then it is essential to consider the cost of the minimum jig to do the work against the saving in labor that might occur with a more expensive one. The balance involves an analysis of the cost of the job per piece and the cost of the labor which will be required to do the work. It is not one for which a simple formula can be set.

How long to keep special dies, jigs, and fixtures depends on the industry. With some products a customer expects to be served with replacement parts for an indefinite period. In others there is no expectation of replacement. In the first case dies, jigs, and fixtures should be kept as long as there is any chance that replacements may be demanded. In the other case they can be thrown away as soon as the job is done. If a product can be expected to last a long time in the hands of a consumer and there is a chance that a few replacements may be needed over a period of years it may be cheaper to throw the die or fixtures away and make the part by hand if the need arises. Here again a careful balance should be struck taking into consideration all factors.

Thus in every phase of equipment selection the important thing, regardless of the type of equipment, is to set up the pros and cons from a cost point of view, and decide in favor of that style, type, and amount of equipment

which will, all things considered, give the *lowest total cost*—that is, *with equal quality of product*.

This is not always so easy as it may appear. It involves intelligent analysis of the product and proper weighing of all factors of initial investment, as well as all factors of labor, material and overhead costs. The test is always, Will this render the greatest possible value for my money in the long run?

CHAPTER VI

RESEARCH, DEVELOPMENT AND DESIGN

By R. G. CASWELL, *Director Department of Industrial Research, Bigelow, Kent, Willard & Co., Inc.*

When it first became known that one of our supercorporations was operating its research department on a budget of \$20,000,000 per annum, with a personnel of some 4,600 charged to research, the news value of that announcement was comparable with that of the dog-bitten-by-man incident. For a time it was felt that the trend was to regard research as the vital factor of industrial progress, which is a gross overstatement of its value.

Research Must Be Correlated with Marketing. A truer picture of the place of research in industry is given by regarding it as only one of several vital constituent factors. Recognition of the real value of research to manufacturing lies in the correlation of this factor of industrial progress with that equally important phase, marketing. Whatever academic interest obtains to this day in respect to the relative priority of the hen and the egg furnishes no parallel in marketing and industrial research. The former, we are convinced, has precedence over the latter. It is recognized that there are instances of a business, or even an industry, that has been founded on a discovery; but in general it is the market survey which first estimates what can be sold, how many can be sold, and to whom and how distributed. These questions of market must, in general, be answered with a reasonable tolerance for inaccuracy before any extensive program of research and process development is undertaken. When this order of development is violated, the stage is set for throwing the whole project out of balance, with the result that the manufacturing organization is likely to find itself possessed of a product, for which it has made a considerable investment in time and capital, and for the marketing of which comprehensive knowledge is lacking. In this situation, the expectancy of profitability from the research is low. Considerations of this character based on experience and observation lead us to the conclusion that one of the primary factors of the organization of a technical department should be the highest obtainable degree of cooperation and correlation with the work of the department entrusted with marketing. To this end, a chart of organization of a technical department would read as shown on page 590.

A Research Organization Must Be Developed. Assuming for the moment the position of a technical department in relation to the company as a whole, its organization and functioning to the profitability of the business it is intended to serve, represents a slow and oftentimes painful process of evolution. Save in rare instances it cannot be developed to function effectively in any

FIG. 1.—Organization of department of industrial research. (Copyright Bigelow, Kent, Willard & Co., Inc., Boston, 1930.)

period measured in weeks or even in months, but must be gradually nurtured with the most painstaking care in the selection of personnel, particularly in the choice of the divisional heads designated as *A*, *B*, *C*, and *D* in the foregoing chart. Obviously, the greatest hazard lies in the selection of the technical director, not only because he is the key man, but also from the fact that the source and authority for choosing him reside with major executives, who in all probability, in the majority of instances, do not possess a technical background.

Wide Variance in Internal Organization. In respect to the internal organization of a technical department, there can be a wide variance in functions dependent upon such factors as the nature of the product and its method of distribution, whether the output be merchandised in bulk or in homogeneous units, or, as is characteristic of by far the major fraction of manufactured articles, as an assembly of many parts. For these reasons no single chart of functions may be drawn to express adequately and without modification to particular needs, all manufacturing. In general, it is felt that an empirical statement of distribution of technical activities is reasonably given by the following breakdown:

	Range, per cent	Average, per cent
A. Research.....	10 to 30	20
B. Development	40 to 50	45
C. Technical service to process.....	20 to 30	25
D. Technical field service and observations.....	5 to 15	10

From this distribution of effort is developed a chart of technical department functions in relation to merchandising and management engineering, which is thought to be self-explanatory.

Outline of Procedure in Specific Case. It is obviously beyond the scope of this article to discuss in detail the application in practice of the many highly diversified cases that are presented to a technical department for solution. These range from a customer complaint for improvement in service of some component part of the product, to a suggestion for modification to anticipate competition and customer demand, and to extend sales by development of a new product. A fairly representative case in point would be to outline the procedure in relation to research, development, and culmination in production, of a request transmitted from the sales department to the technical department to develop a perforated rubber soap container in imitation of veined marble, say Egyptian porphyry. Let us assume that the director of merchandising has first determined probable market for the proposed new article of manufacture, together with the cost of sales and margin between sales cost and sales price, in the absence of which information the technical director would do well to reject the project. Let us further assume that the company has experience in the manufacture of mechanical rubber goods, and that the contemplated bath soap container does not entail divergence either in manufacture or in distribution.

The initial step in the creative process would be assigned to the research division, which would possess satisfactory resistance to light and air aging, would not stain, would manifest a permanent bright surface under service conditions, and would be free from sticking and

Fig. 2.—Research functions in relation to merchandizing and management engineering. (Copyright Bigelow, Kent, Willard & Co., Inc., Boston, 1930.)

chipping during the hot moulding operation. Formulae to yield the veining effects and shade of color would also be a part of the research. In addition, the division would be expected to submit material costs, estimates of probable losses or rejects, and equipment productivity based on the cycle of vulcanisation. At this stage in the art the development division would

undertake the design of multiple moulds, and eventually standardize the mixing of the raw stock, calendaring to gauge with establishment of tolerances in thickness and shape of slug for the mould; and carry out the operation for producing the finished article on a semiworks scale, until a fair picture of manufacturing specifications and total manufacturing costs was available. Finally, an engineer from the development division would cooperate with the production department until the article was finally accepted as a regular routine manufactured item.

The same procedure obtains when the proposed betterment work relates to the design and development of special tools and equipment. In many organizations work of this character is carried on by an experimental mechanical division of a strictly engineering department. But adequate provision for this type of development exists in a technical department that contains a development unit as given by Fig 1. It is our thought that a single technical organization should embrace all technical activities, including:

1. Research.
2. Development.
3. Technical service to process, commonly designated as control work and "trouble shooting."
4. Technical field service.

We believe also that the differentiation in respect to work should be in terms of the character of the proposed betterment project as outlined above and not in terms of the particular field in which the development lies, as for example the chemical, the chemical engineering, or the mechanical.

Scope of a Technical Department. The objection to the last-named classification as a basis of organization is that, by and large, problems are not clearly separated into these lines of attack, and that operation under these conditions entails considerable overlapping. There is frequently a broad and indeterminate borderland between the chemical and engineering phases of a problem. In this situation it is our thought that a more effective and flexible basis of organization obtains when the physical set-up of the department is formulated upon the conception of the problem as advancing by stages, and that the problem is held to be neither chemical nor mechanical, but one of development. From these considerations it would appear that there are marked advantages in concentrating the direction and control of all technical betterment work in a single technical unit, in virtue of which a problem gradually emerges from the research stage to enter the development stage, and thence to the semiworks trial period, without undergoing any disruptive influences that would otherwise be likely to be encountered by transfer of authority to an outside department. In a technical unit embracing research and with full authority for development, the internal transfer of personnel to meet special needs is readily and effectively accomplished. It is for these reasons that the concentration of all technical functions within a single group is favored.

It is not intended from the foregoing picture of the scope of a technical department to steal power from the engineering department. The latter has a distinctive function in any large manufacturing organization. Problems of equipment maintenance and replacement, the extension of operating and

service units, construction and demolition are some of the activities which are unquestionably applications of the engineering art, and are entirely without the field of product and process betterment.

Importance of Semiworks Study. For the actual carrying out of technical process work, it has been the experience of many manufacturers that there has been a progressive increase in the size and investment in equipment for use in experimental work, and this condition has culminated in the recognition by those manufacturers better organized and equipped for the prosecution of technical activities, of the need for a set-up between the laboratory and plant, and to which the term semiworks has been given. It is true that in many instances the results of the laboratory can be translated directly into plant operation, or when adjustment to factory process and equipment requires a trial period under conditions approximating regular operating conditions, that this development work can be carried on in the plant without serious interruption of production. But it is more likely to be the case that preliminary trial of contemplated change in process or product under factory conditions will indicate the necessity of revamping the equipment, which may conceivably entail major changes. The attendant expense in view of the hazard of failure of the experiment in relation to the volume and value of the material involved in the plant scale trial, calls for rare good judgment and a certain measure of good fortune in this kind of experimental work.

It is an empirical fact that, generally speaking, a semiworks as a place for trial manufacture under conditions entirely apart and distinct from the plant cannot be economically eliminated from a well-rounded technical unit. Instances of the failure to appreciate the necessity for semiworks study as an intermediate stage between laboratory and plant have been numerous within our observation over the past fifteen years. A case in point that occurred during the progress of the first assignment ever tackled by the writer is felt to be fairly representative of the error in not including a semiworks in the technical program. Attempts were made to translate observations made in a 10-gallon kettle to regular operation in a 3,000-gallon tank, in the course of which problems of agitation and rate of heat transfer in relation to chemical action and crystal formation developed obstacles of such proportions that after much waste of time and material it became necessary to reopen the project virtually as a new study. Some years ago, in the course of a discussion on this point with the general manager of one of our largest corporations engaged in the manufacture of acids and heavy chemicals, it was stated in reply to a question by the writer that in respect to the order of difficulty in development, the ratio 1:10:100, represented his experience in the ascending relationship of laboratory to semiworks to plant. Herein is a rough picture of the responsibility and comprehensive scope of a technical unit.

Summary of Functions in Sequence. A description of the coordinated interests of a technical department operating through the laboratory, the semiworks and the manufacturing plant in the bearing of these three constituent functions on the profitability of the technical department to the company, may be summarised in the following three paragraphs:

The Laboratory. Here the bibliography, including patent literature, is first searched for suggestions and data pertinent to the project. This is followed by experimental work to determine the fundamental chemical and engineering properties involved, particularly with respect to limiting variable factors of process and product, and estimated material costs.

The Semiworks. At this stage in the research, the development of process is studied on a semicommercial scale. Here are worked out the problems of handling of solids and liquids; selection and layout of equipment; problems of heat transfer, agitation, and mixing; the combating of corrosive influences; the apportionment of direct and indirect labor, and the probable necessary technical supervision and control. From this experience in the study of process on a semiworks scale, there is obtained reliable data for the design and construction of plant.

The Plant. In this unit is verified the scientific soundness of laboratory study, the practical experience of a period of reduction to practice on a semicommercial scale, so that the culmination of development in the plant insures uninterrupted production at economic manufacturing cost.

Patent Not Always Desirable. The desirability of obtaining patent protection on improvements which constitute invention presents a question that is open to much discussion. In theory, the amount of protection is a straight line function of the degree of disclosure, so that it logically follows that a patent is no stronger than its disclosure. But the nature of the protection afforded the patentee in virtue of his disclosure is limited to the privilege to seek redress at law against an alleged infringement. The possession of a patent, therefore, can in no sense be construed as an equivalent of insurance. The manufacturer, in order to defend his patent merely has the right to recourse to legal action. There are conceivably instances in which infringement has been existent over a fair fraction of the life of the patent and without the patentee's knowledge; or cases in which practice is based fundamentally on a patentee's disclosure, but in which the factor of resemblance to the patent falls just short of that degree of similarity to render the case actionable.

As a fruitful source of suggestions for a research project in its initial stages, the situation is further complicated by the fact that the study of patents is generally held to be of equal importance with that of the general technical bibliography.

Considerations of this character, however, should not be taken to discourage a manufacturer from seeking a limited monopoly for his invention in exchange for disclosure, particularly in view of the fact that he cannot altogether escape from the hazards of disclosure through leakage.

On the contrary, there are numerous cases in which the useful invention is basically new, and these it is generally practicable to cover by letters patent. It is the purpose of this brief review merely to differentiate between those subjects that embody a fundamentally new product or process that is of intrinsic value to the prospective patentee, and those minor improvements in process or product, which are difficult to defend against infringement and for which the expense of securing patent is frequently hard to justify in value received.

Here again a heavy responsibility rests with the technical director. It is obviously his duty to stimulate creative effort in the staff under his control,

and to this end he cannot categorically refuse to the inventor public acknowledgment of his invention in the form of letters patent. Withal, it cannot be controverted that the phraseology of patent specifications, in which the thing or art for which protection is desired, is described as a "useful invention" is, by and large, tremendously flattering. Anything approximating a *laissez faire* policy in this respect would soon lead to a condition, in virtue of which the company might be working primarily in the interest of its patent attorney.

Economic Point of View. Some decade and a half ago, an instructor in McGill University asked of his class of twenty-eight men in chemical engineering, this question: "What is a chemical plant for?"

Twenty-seven of the replies averred that the reason for the existence of a chemical plant ranged from furnishing concrete illustrations of the principles of science, to the advancement in the industrial arts in the interest of society; all of which answers reflected an academic and commendably scientific point of view.

The twenty-eighth reply was the sole expression of the cogently imperative economic viewpoint, expressed in Coolidgean terseness, "To pay a dividend."

To this end, and to this end only, the plant operates in the interest of the workers and capital employed, and the public that is served by its output. The continuance of profitability is the "be-all and the end-all" of its existence. The technical or betterment department as a factor of maintaining and improving the position of the company in relation to profitability must have an identical point of view. This conception of the broad function of the technical department in no sense entails a perversion and degradation of the scientific approach and attitude. On the contrary, it merely sets the stage for concentration on those problems from which the expectancy of adequate return is high.

The questionnaire by which the ancient Greeks tested all new propositions may be recalled in this connection:

1. Is it true?
2. Why is it true?
3. What of it?

Academic research, which has its roots in speculative philosophy, is logically interested to submit an answer to all three propositions, in the order of their presentation. Industrial research, on the other hand, must concentrate on propositions one and three, and during the period that it is struggling to determine the truth or falsity of a hypothesis it must visualise its value in application by replying to the vitally economic test question, "What of it?"

Research Appropriation Based on Gross Sales. From these considerations, it remains to determine what economic factor shall be selected for measurement of the size of the appropriation for the work of the technical department. As a general principle, we have laid down gross sales as a reasonable basis for expenditure to this end, and have taken 1 per cent as a minimum empirical ratio of industrial research to gross sales. In Fig. 3 we have plotted expenditure for technical work against gross sales over a range of \$500,000 to \$10,000,000 per annum. Obviously, this percentage will be likely to

exceed 1 per cent as the gross sales are progressively less than \$10,000,000 per annum. Ratios as expressed by this chart are empirical and cannot be held to have justification other than such as has been derived from observation and experience.

Average Costs per Man per Annum. In general, it has been found that total cost per man per annum, including staff, supplies, equipment, and

FIG. 3.—Expenditure for research vs. gross sales. (Copyright Bigelow, Kent, Willard & Co., Inc., Boston, 1930.)

general expense, approximates \$4,000, although wide variations in this respect have been noted. An instance in point is furnished by a technical department operating under five subdivisions, in which the divisional costs per man per annum varied from \$3,000 to \$4,600. Apart and distinct from variations in cost per man per annum within the groupings of a single department, there will exist a wide range in the average costs per man per annum among the technical organizations of different companies. These variations follow in part from wide differences in the nature of the development work, in the cost of equipment and supplies, and in the experience of the personnel required. But, in general, it would be anticipated that in a company having annual gross sales of \$5,000,000, from \$50,000 to \$54,000 would be expended for the technical department, including a staff of twelve to fourteen men.

Control of Expense of Research. One of the most perplexing and troublesome problems that has confronted administrative officers in the management of their technical departments has been the disposition of the research budget and control of expense in relation to accomplishment. It is our thought that the organization of a technical department, not only from a physical, but also from a cost standpoint, approximates in importance the emphasis that attaches to the actual prosecution of technical work. For where recognition is not given to distribution of effort and its attendant expense in the bearing of these factors on profitability, the department is likely to be out of balance, with consequent over-running of appropriations, through the carrying out of work from which adequate return is not forthcoming.

Accounting Difficulties. In so far as we have been able to ascertain, no comprehensive or even adequate system of accounts for the crediting of the achievements of a technical organization has ever been worked out. The development of such a system to embrace all technical activities is a thing of the future and current procedures must be regarded as formative and tentative. This condition follows from the fact that the results expected from technical work are only in part tangible, and capable of being evaluated as a definite credit against the expense of research. From this conception of the functions of industrial research, the following subdivision of activities affords a basis for a partial reduction of expense to a method of accounting:

A. Tangible.

1. Process savings.
2. Reduction in material costs.
3. Reduction of waste.
4. Disposal of waste and by-product material.
 - a. In process.
 - b. By conversion into marketable products.
5. Sale of patents or royalties from same, or manufacture.

B. Intangible.

1. Solving of process troubles to insure uninterrupted production.
2. Development of control tests to safeguard present quality.
3. Maintenance of technical control.
 - a. Raw materials.
 - b. Materials and products in process.
 - c. Finished products.
4. Improvement in quality, appearance, and versatility of product in service.
5. Extension of sales through new products, to anticipate competition and to meet present customer demand.

It is felt to be safe to assume that the so-called intangibles outweigh in importance the tangibles, from which condition the way is not clear to set up a technical department on a 100 per cent accounting basis, but only to the extent of definite savings classified as tangibles. The balance of research expense is charged off to product and market betterment.

This type of apportionment of technical department expense follows from a conception of the scope and function of technical work that has no theoretical basis, but has its origin solely within our observation and experience. It is our thought that marketing and industrial research are highly interdependent

factors of industrial progress, from which conception it is held that a technical department should not be forced to justify itself entirely in terms of definite economies accruing from its work; and for which reason a definite percentage of gross sales, say a minimum of 1 per cent, should be appropriated annually for the promotion of product and market betterment.

Incidentally, experience has shown that in not a few cases in which the technical department has been properly organized and its program efficiently carried out, the expense of the department is in large measure balanced against the savings obtained from the so-called tangibles, leaving only a small residue to be charged off to product and market betterment.

Method of Evaluating Accomplishment. The problem, then, is how best to evaluate accomplishment, particularly in respect to the intangible group of technical department functions in relation to expenditure; and how best to set up and control expense. For this purpose the establishment of all technical department activities under a docket, with the respective jobs under the docket designated as projects, furnishes the groundwork for a simple, workable and consistent scheme for research control.

A skeleton form for projects is given below:

Title of Corporation			
Technical Department			
Project No. _____	Date approved _____		
	Date work started _____		
	Assigned to division _____		
Object _____			

Prior art _____			

Estimated cost (monthly, when final cost for completion cannot be estimated)			
Estimated date completed (wherever possible)			
Estimated economies (if in the tangible group—annual basis)			
Status of project:			
Month, 1930	Per cent completed	Expenditure	Progress to date
_____	_____	_____	_____
_____	_____	_____	_____
_____	_____	_____	_____
If discontinued or in abeyance: Reason _____			
(Date) _____			

The formulation of the projects under the docket is the duty of the technical director in collaboration with the directors in charge of manufacturing and of merchandising, and the comptroller. In addition to its major purpose in evaluating the cost of technical work, the docket system furnishes the means for determining a capacity load for the department, and for the fixing of responsibility, in the event of a change in, or discontinuance of, any of the items of the docket.

Use of Monthly Time Sheet. For the determination of monthly costs, the basis is a monthly time sheet supplied to all members of the technical department, including the director. The function of this time sheet is not to serve as a check on the amount of time spent on the company's premises, so that it is in no sense an attempt to create a palatable substitute for a time clock. To the technical staff this time sheet presents an incentive to effort, it is thought, more cogent than the ordinary time recording devices, in that the technical worker records his own distribution of his time to the projects to which he has been assigned. Assuming an eight-hour day for five days of the week, and four hours on Saturday, the established hours in any given month might total, say 180 hours. Work is prorated to this arbitrary period. Absence from work, although noted on the time sheet, is charged to projects, inasmuch as the projects must bear the expense, since salary is not deducted for absence. If a worker toils well into the night, he records no overtime, because he is not paid for it.

A skeleton form for this monthly time sheet, together with dummy projects, is submitted on page 601.

There is no hazard of disclosure of salaries among the staff through the medium of the time sheet, which is transmitted to the technical director and from him to the comptroller for calculation of distribution of staff expense (salary) to the respective projects.

Supplies against requisitions are charged directly to the projects for which they were ordered, and any items of equipment expense that cannot be capitalized are handled in the same manner. The items of general expense, such as power, light, heat, steam, water, cleaning, taxes, insurance, and depreciation, which may be broken down into as many accounts as is desired in any particular case, are prorated to respective projects in the same ratio that the staff expense charged monthly to any given project bears to the total staff expense.

From these monthly data there can be prepared a statement of technical department costs, monthly and accumulative, which yields an accurate picture of expenditures by men, by divisions and by projects, in relation to estimated accomplishment of the task.

In respect to analytical and control work in process, the horizontal headings on the time sheet indicate the department for which the work, primarily routine and repetitive, was performed. In some cases it has been found to be advisable to separate the analytical from the control work, since in the laboratory not all of the analytical work is for control of factory process. This differentiation is readily made by placing before the particular department designation for which the work is carried out, the letters *A* or *C*.

(Title of Corporation)

It has been found by experience that the clerical work of tabulating and organizing the monthly cost sheet is not excessive; an instance is recalled in which four hours by one cost clerk were required for handling the complete breakdown of monthly costs for a technical staff of twelve men.

The increase in effectiveness resulting from the employment of a method of this character for the control of experimental work, follows in part from the knowledge and incentive given to the individual worker of the monthly and accumulated expense of the project in relation to accomplishment. To the administrative officers, it presents an equally terse statement of status of projects in terms of expenditure.

There is no alibi for the administrative officer operating under a docket system of research control. He has before him an exact statement of expense charged to each project, and he is at liberty to modify as he may choose the technical department's own estimate of its progress, as expressed through a monthly progress report. Decision clearly rests with him as to the worth-whileness of continuing any particular project or of placing this project in abeyance.

It is recognized that no scheme of research control can provide a medium in virtue of which results may be guaranteed in advance. The aggregate expenditure and time required for completion are equally difficult to predetermine, save where prior work in a particular field has furnished experience from which such an estimate can be made. But obstacles of this character do not prevent the practicability of setting up a monthly or quarterly budget, divided into projects, with estimated costs for staff, supplies, equipment, and general expense; and the checking against this budget of actual expense incurred. From a system of control of this character, it has been our observation and experience that there results a tremendous increase in effectiveness of industrial research. Action to this end is becoming increasingly imperative, in view of the wider publicity given to research and the closer scrutiny to which this and other non-manufacturing departments are being subjected.

Time Limit for Crediting Saving. Over what period a reduction in cost, resulting from the successful termination of a research project, should be considered as a saving, follows as a corollary from the foregoing discussion. Considerable latitude must be assumed in determining this point, depending on the particular nature of the development. If no competition in research existed, the period during which a reduction in cost could be taken as an economy might be extended indefinitely. Where competition in research is acute, a maximum of six months might be the limit. Between these two extremes, it is felt that a period of one year may safely be taken as the basis for the calculation of an economy brought about through research. Most research problems, in which the objective is not one of quality but of lowering of cost, resolve themselves into a number of projects of narrower scope that can be consummated within a twelve-month period.

The fixing of a time limit of one year as the basis for the crediting of a saving, constitutes an incentive for the technical department to concentrate its efforts on the purely profit-bearing possibilities of the project. It is of further advantage to the technical director in guiding the choice of projects

in which the potential volume saving warrants the attention of the technical department.

Growth of Organized Research. Two generations ago the achievements of research were in the main the products of individual inventiveness, and with the exception of academic groups working under the direction of a university professor, the figure of the research worker in industry was that of the genius toiling by himself, and to a large extent isolated from the business as an organization. Under these conditions, the set-up was tantamount to that of the free lance, and much work was carried out that was tangential to the real economic purpose of the investigation. From that day the trend has been steadily towards organization and directed effort to predetermined ends, so that the status of industrial research has gradually become less and less that of a wild gamble, the expense of which was chargeable to profit and loss, and progressively more and more that of a recognized subdivision of industrial activity, and as such, reducible to management.

Paradoxical as the statement may appear, it is our thought that the world has been continuously, from the most prehistoric ages, research-minded, and that this condition as a constituent factor of evolution will in all probability continue until "the last syllable of recorded time." The epoch-making era of research, into which we have only of late entered, does not signify that we have just begun to sound out the sources of wealth through experimentation, to the degree that it denotes that we have of a sudden become appreciative of its value to industry as a factor of insurance. It may be recalled in this connection that a personage of no less importance in the political and social life of the sixteenth century than Elizabeth, Queen of England, was oftentimes obliged to go to bed in the daytime in Windsor Castle in order to keep warm; and that this hardship occurred during an age in which the textile arts, painting, sculpture and ecclesiastical architecture were undergoing tremendous development. Nearly a century and a half elapsed before Franklin brought the fireplace out into the room, and demonstrated to the world in the stove that bears his name, that being warmed was not as much a matter of fuel supply as of direction and rate of heat transfer. It is not illogical to assume that if the sixteenth century mind had possessed the research consciousness of the present-day world, there would have been installed in Windsor Castle before the beginning of the 1600's a tolerably good hot-air heating system.

Progressives throughout the world are ever looking to the day when there shall be created that ideal republic visualized by Plato, wherein "wealth shall have no authority, and authority shall have no wealth." In this well-nigh Utopian scheme of things, to which the most advanced radical thought offers no suggestion for accomplishment, the progress of research, and particularly that of industrial research, has considerable bearing. For it is by the gradual elimination of all hand labor, and the tapping of new sources of wealth through research, that approach is made to that day "when the shuttle shall weave, and the lyre shall play, without the aid of human hands; then, and not until then, shall all men be free, and there shall be neither masters nor slaves."

CHAPTER VII

PRODUCTION CONTROL

BY GEORGE T. TRUNDLE, JR., *President, and THE STAFF, Trundle Engineering Company*

There is perhaps no other single factor in industrial management, having equal importance, which is so much misunderstood as production control. There seems to be so much confusion about its scope. There is certainly a disturbing disagreement as to terminology and definition. "Planning," "routing," "scheduling," and "dispatching" each may mean different things to as many different individuals. Systems are so often confused with principles. Forms are accepted as fundamentals. Routine is taken for results.

This discussion covers one of the most important and far-reaching functions in the management of industry. Nothing influences every factor—labor, material, equipment, and product—quite so thoroughly as does production control. To its lack or ineffectiveness much waste, much loss, and many failures in business can be traced. It is a powerful and profitable mechanism when properly applied, a dangerous tool if misapplied.

This is an endeavor to present the conclusions and findings growing out of experience in several hundreds of industries where earnest and serious efforts were made to effectively control production. These are offered with the full realization of the fact that others have had other experiences which may have led them to other and different conclusions.¹

Major Divisions of Production Control

Planning. Planning is used perhaps more often than any other term to describe production control. This is due, no doubt, to the fact that in the original conceptions of a specific and separate function of production control

¹ See for details on the technique of production control:

BASSETT, WILLIAM R., and JOHNSON HEYWOOD, "Production Engineering and Cost Keeping," McGraw-Hill Book Company, Inc., 1922.

DIEMER, HUGO, "How to Set Up Production Control for Greater Profits," McGraw-Hill Publishing Company, Inc., 1930.

HALLOCK, JOHN W., "Production Planning," The Ronald Press Company, 1929.

LICHTNER, W. O., "Planned Control in Manufacturing," The Ronald Press Company, 1924.

RAYMOND, FAIRFIELD E., "Economic Lot Sizes," series of six articles in *Factory and Industrial Management*, McGraw-Hill Publishing Company, Inc., July-December, 1930.

YOUNGER, JOHN, "Work Routing," The Ronald Press Company, 1930.

in organization, the idea of a plan made in advance of performance was one of the principal innovations from old practice. Production planning was recommended and planning departments were created, but the modern conception of management now includes planning as a stage in *every* phase of management and in the management of all things and all functions in the business.

Planning therefore, has become a principal element in all management. It cannot, and should not, be confined to production alone. It is too broad a term. The blue print is a plan of what to make. There is, or should be, a market plan. Sales quotas are plans. The plant layout is a plan. Cost estimates as well as standard costs are plans. The financial forecast is a plan of profits.

In addition to this, modern management goes much further than the plan itself in the control of production, and prescribes that it must also include the guidance of production throughout all the stages from the receiving platform to the shipping platform, and the coordination of all the factors at each of these stages, in order to accomplish the plan according to the time schedules.

Planning therefore, as a term, is too broad on the one hand, to be confined to production control alone, and on the other, paradoxically, it is entirely too narrow to describe the complete process of production control.

Routing. Routing is one of the elements in planned production. It prescribes the path of travel of production in the plant layout. Where this cannot be standardized, and where changes in the work itself, or in the daily production requirements cause daily or current changes in the path of travel, it becomes one of the mechanisms of production control, used continuously in dispatching work along this path of travel to the work places.

Under standardized conditions it endeavors to prescribe the shortest path of travel and to carry the work to that equipment and to those operations where it can be performed most economically. Standard route sheets must be coordinated, by production control, in the production schedule with the time element and with the quantity element, in such a way as to accomplish the desired result without confusion.

Under conditions not standard, production control continuously routes the work daily and periodically, thus combining the place element and the time element in the daily production schedule. In doing this it also endeavors to route over the shortest path of travel and to the most efficient equipment and operations, although in this it may often be found that, to meet the time requirements, work must be routed to the next best equipment and operation, and constant adjustments must be made to secure the best results from the available plant capacity.

Routing is usually entirely separate from production control, but may in some cases be a current part of production control and a daily duty.

Perhaps because of this variation, there has been some confusion as to this term. Recently a magazine article reported that a manufacturer had discarded production control. A careful reading of this article proved that what had really happened was, that having reached a large production of a standard product, it had become practical to make standard route sheets for the path of travel of the work. This has often happened and is happening constantly

in growing businesses. The point is, however, that standard routing does not take the place of production control, although it does usually simplify it.

Scheduling. Strictly speaking, a "schedule" is a list. There are schedules of freight rates, schedules of ocean sailings, etc. When applied to manufacturing, the schedule is a list of parts to be made, often in a prescribed sequence, and sometimes within a specified period.

Scheduling production then, is really listing requirements of what shall be done. It is one of the mechanisms of production control, a medium used in laying out the plan of work, but by no means is it either the whole plan itself, nor is it control, for it must always be followed by some activity to see that the schedule is put into effect.

Because it is one of the tangible evidences of a plan, and one of the visible indications of production control, scheduling is sometimes used to describe the entire function. It should always be remembered that the preparation of a production schedule does not provide production control. The technique and act of doing the work must be added.

Dispatching. Like scheduling, dispatching is one of the mechanisms of production control, but not the control itself. Dispatching properly means starting something on its way, sending it along toward some destination. In factory parlance, it usually indicates the method or process of assigning work to definite work places, and where necessary, accelerating or retarding its progress from point to point. This is its limitation. It is a current process, part of the whole, and an important one, but never to be expected to do the entire job of controlling production.

There are manufacturers who are satisfied that they have production control, when as a matter of fact, they really have only a dispatching system, or a follow up scheme, or an order chasing plan. No matter how good these may be, they are not in themselves production control.

Production Control Best Term. So we find that none of these four terms are descriptive enough, comprehensive enough, or accurate enough, to cover what is and must be included under the control of production in modern management.

What term can we use? There would seem to be no alternative than to use the term production control as most descriptive, comprehensive, and accurate for our purpose, having it understood that in so doing, the following definitions and limitations are intended.

Production Control Defined. Production, as used here, is meant to include all the processes of converting raw material into a product ready for delivery to the purchasers, usually, although not always, including the purchase of the raw material itself; usually, although not always, including the storage and the inventory of raw materials, semifinished parts and finished product; but always including all of these, where they in any way influence the continuity of the actual production that is necessary to accomplish a given result in a given time. Roughly, it is synonymous with the term manufacturing.

Control, in its broadest sense, is synonymous with management. To control is to direct or to restrain. Used in that sense, production control might mean the management of manufacturing. But that is not intended here. It would be too broad a definition, for it would include quality control

(inspection) and cost control (accounting) and methods control (production engineering, etc.). Production control does not properly include these.

Production control is concerned, primarily with the *time* aspect of manufacture. It may, and often does, combine with this, the *place* aspect, although this is really a separate problem in most cases to be determined elsewhere. It also combines the quantity or volume aspect with the time aspect.

To summarize, we find that production control uses all information which is furnished, indicating: (a) what is to be made; (b) from what it is to be made; (c) where it is to be made; and (d) how it is to be made; and then determines itself *when* it is to be made and proceeds to control this performance.

This is, of course, the ideal condition. There are variations from it. But, in so far as it is practical, production control is, and should be, allowed to concentrate only on those factors which involve the time element in manufacture.

The Need for Production Control

The report of President Hoover's Committee on the Elimination of Waste in Industry stated: "The lack of adequate methods of production control is evident in every industry studied. It is one of the outstanding weaknesses." This report was made after studying major industries, and is evidence that production control had not yet been accepted in principle by important industries.

The findings of the committee are significant, when we remember that those who have had ripe experience with adequate applications of production control, have come to know that it is a necessity and not a luxury; a profitable investment and not an expense.

Service to Customers. Production control endeavors to give the best service possible, consistent with available capacities, and at the same time to secure the lowest possible costs. In addition, it tries to balance these two factors so well that the first is not accomplished at the expense of the second, and *vice versa*.

Although service to customers cannot be evaluated in dollars and cents, it is nevertheless accepted as having great profit and loss potentialities. For this reason, and sometimes also because the sales department is permitted to emphasize this feature as important to sales volume, the service requirements are usually placed ahead of costs.

Without in any sense intending to detract from the importance of service to the customer, it must nevertheless be admitted that there are cases where service has been secured at a cost out of all proportion to any possible gain. This occurs, for instance, where the steady flow of production is constantly interrupted by "special" or "rush" orders. In other cases it occurs where a stock is carried in quantities too large for current needs or consisting of items moving too slowly, with the result that too large an inventory is carried with too little turnover. This is often a cause of large hidden loss.

Production control, therefore, recognizing the loss described coming from inadequate service on the one hand, and too costly service on the other, endeavors to provide the flexibility in the flow of production necessary for

adequate service, and also endeavors to provide the limitations of expensive interruptions in this flow of production. This requires many compromises and can be accomplished only through the application of much good common sense and impartial judgment. The net profit to the Company in the long run must always be the deciding factor.

Securing Lowest Costs. Aside from the matter of service, production control aims at lowest production costs possible under existing conditions and with available facilities. This, when analyzed, means the following:

1. Plant equipment must be used to its utmost capacity on that work which it can do most economically.

2. Plant space must be used to its utmost capacity, at the same time eliminating congestion which might hinder the orderly and rapid movement of material or the efficiency of operations.

3. Sufficient labor must be provided and used to its greatest effectiveness on operations where its training and experience can serve best, and where it can earn for itself and for its employer the greatest possible return, eliminating all avoidable delays or waits for materials, tools and equipment, instructions or the like, and reducing labor turnover to a minimum.

4. Work must be put through in carefully computed economical lots, reducing set-up cost and too frequent changes in operations.

5. Raw material must be provided in proper quantities at the right time and at the right place, to prevent, on the one hand, delays in production, and on the other, congestion on the factory floor.

6. Work in process must be moved promptly from one operation to another in proper sequence to eliminate waits at work places and prevent congestion on the factory floor.

7. Product must be finished in proper quantity and of proper quality, and in satisfactory variety to comply with the requirements of customers, without creating unnecessarily large or slow-moving inventories.

8. All the above factors must be coordinated to create a smooth and steady flow of production, synchronized with requirements both as to quantity and quality, and balanced to provide both adequate customer service and lowest possible production costs.

A careful consideration of the above leads us to the conclusion that production control is, more than anything else, the persistent coordination of many variables. Its importance and effectiveness would therefor seem to increase in proportion to the increase of these variables.

Three Principal Losses. When coordination does not exist, losses of three kinds, are usually found:

1. Losses due to the failure to use plant facilities including space, equipment, and labor to their fullest capacity and effectiveness. These are the full responsibility of production control except, of course, where the sales requirements are less than the real capacity provided.

2. Losses due to unnecessary delays, waits, interruptions, and readjustments in the flow of production due to lack of materials, insufficient labor, lack of tools, jigs, and fixtures; lack of proper equipment available at the right time; lack of, or incomplete, instructions; too frequent set-ups and changes in operations; and uneconomical lots. All these are entirely the responsibility of production control.

3. Losses due to carrying excessive or unbalanced inventories, either of raw materials which might be caused by poor synchronization or lack of intelligent preplanning; or of work in process, caused also by poor planning or else by failure to move material in process promptly or in an orderly manner, or by improper lot sizes; or of finished goods, caused by improper lot sizes, poor coordination of operations, having work in process too long, or lack of intelligent preplanning. All these losses, often not evident unless carefully investigated, and in many cases quite large, are also the full responsibility of Production Control, except where they are influenced by general policies as to (a) advantageous purchase of raw material when favorable prices prevail, thus accumulating stocks above normal, or (b) maintaining unusually large and diversified stocks of finished goods to meet peculiar service requirements and to facilitate selling.

Summary. The following are reasons for providing adequate production control of manufacturing:

1. Because competitive manufacturing today demands orderly procedure and controlled management.
2. Because service to customers, which has become a profit and loss factor, must be controlled so that it is neither inadequate on the one hand, nor too costly on the other.
3. Because it is necessary and advisable to secure the extra profit representing the difference between actual costs and possible minimum costs, which can be secured by eliminating the losses caused either by failure to use plant facilities to full capacity, or by avoidable delays and interruptions to the smooth flow of production, or by carrying an excessive or unbalanced inventory of materials, or to all three of these influences.

Essentials for Complete Control

There are four main essentials, which are needed regardless of the size or type of the operations, to make the application of production control complete and fully effective. They are discussed in the following:

1. **Should Cover Every Factor.** The control needs to be entirely comprehensive, should cover every detail, and apply to every factor which has even the slightest influence upon the final results.

It is not enough to have an order system and to plan and control the sequence of the orders. Back of the individual orders, the general plan of production for the company as a whole should be developed and planned. Then the general production schedule and the master schedule is to be developed and planned, all in sufficient detail and so flexible that the influence of the individual order can be seen as regards the whole requirements, and so that all the orders may be given their proper places in the whole program and thereafter easily changed from one position to the other as required by changing demands.

Each order should be broken down, the operations needed for its execution analysed, their sequence established within each order and then within the whole production program. The performance is then to be controlled not only up to each department but right to each individual operation and machine.

In other words the control of orders should go back as far as their acceptance and then forward to the last operation and machine needed for their production, and preferably for their shipment to the customer.

Neither is it enough to control and plan only the manufacturing operation; material, labor, tools, jigs, and fixtures, blueprints and instruction, and every single element affecting performance should also be covered by the control plan. Nothing less than complete control of all of these factors will suffice. This control should be both comprehensive and detailed. It should take nothing for granted. Under no circumstance should it be denied access to any one of these factors.

2. Right Kind of System. There should be provided sufficient of the right kind of system, forms, and clerical routine to (a) collect adequate detailed information needed for planning; (b) inaugurate work and give complete instructions and the detailed information needed in performance; and (c) provide records of current and past performance.

These records should be prompt, adequate, and usable. Only enough system for the purpose should be installed. Any more than is needed constitutes the much to be dreaded "red tape" which only makes for confusion and congestion. Duplication is to be watched for and avoided.

Nor should any of this system or any of these records be considered any more than tools. They are inflexible until judgment is applied, and flexibility is one of the chief requirements for adequate control. They are servants; never masters. They aid, but in themselves never control anything.

3. Competent Personnel Properly Authorized. Sufficient personnel should be provided and given proper authority so that its influence will be wide enough to get the desired results.

How much personnel will be needed depends upon the size of the operations, but it should never be cut to such a degree that it cannot function properly or cover all details essential to full control. On the other hand, it should not be larger than is needed, nor more expensive than can be justified by possible returns.

This personnel should be placed in such a position in the organization that its influence in its field will never be questioned. On the other hand it need never be given any authority beyond the scope of its particular field. Never should its responsibility be hampered by petty jealousies of other members of the organization, or by lack of support of the management.

This personnel should be trained to handle the work properly. Incompetence or lack of force will soon defeat the purpose of the plan. It should realize its place in the organization, the importance of its work, and be inspired by a genuine desire to serve all the functions with which it comes into contact.

4. Proper Spirit. Finally, and of no small importance, is the inculcation of the proper spirit in the entire organization from the president or general manager down to the last man in the factory.

A position should be given to production control in the organization, designating it as one of the major functions. Other members even including the general management should be made to respect this position. The general management and all others are to work through and not beyond it with respect to all factors included in its scope. If it is considered in any way superfluous

it should be thrown out; it no longer serves any purpose. If it is considered too weak, it should be strengthened. It should never be permitted to just "get by." It needs to be a force, a strong influence, a factor to be reckoned with in every step of the whole job of producing.

To gain this respect and protect this position, the staff undertaking the work of production control should through its industry, its tact, its respect for and reference to the judgment of others, its intensive application to its own job, its force in securing compliance with its stated requirements and its own willingness to defend, aggressively, that which it knows is necessary for greatest results, prove to all the other functions that, while it is considerate of them, it is also competent to do its own job and will insist on being permitted to do it.

This intangible thing—the right spirit among those who undertake the work of production control and among all those others with whom it comes into contact—is so important that, unless it can be attained and maintained, production control should not be attempted, for it is doomed to failure even before it starts.

The four essentials to complete and successful production control are: (a) comprehensiveness, (b) right kind of system, (c) competent personnel properly authorized, and (d) proper spirit in the organization.

Installation of Production Control

The General Plan. A general plan exists in every business. It may in some cases be unwritten and not easily recognized, but if it is no more than the expression of current policies of the company, no matter how vacillating, it does exist. In other cases, often of necessity, the general plan is carefully laid out; it is written; it is a rule and guide, sometimes even the absolute law of the company. It is a simple thing in some businesses—very complex in others.

With all its wide influence, this general plan is sometimes a matter of tradition and precedent. For instance, there are companies which for years have made an established quantity of certain products regularly for the same customers, according to the same specifications and quality requirements. It is expected that exactly the same thing will be done in the future. That is their general plan.

In other cases, there are companies which never know from day to day what orders to expect and what demands will be made upon their manufacturing facilities. They may produce various grades, sell in large and small quantities and comply with all sorts of demands from their customers. It may be profitable to do so. Their plan is hard to set down, it is involved and intangible. But this very vacillation and demand for instant flexibility is the expression of their general plan.

Somewhere between these two extremes are found the conditions in the majority of manufacturing companies, where there are established policies as regards what to make, what quality, what varieties and at what seasons. They also have estimates of their productive capacity either in the form of standard production rates or at least general estimates of some kind. They

have some knowledge of what to do except in the way of orders. This information may be general or may be secured from well laid out sales quotas. A general plan is usually written to cover all these expectancies. If it is not written, it usually can be, and should be.

To set up the general plan is the first step in production control. The general plan is in fact a sort of spinal column of the production control plan. If the first is weak, so will the second be. If the general plan is well laid out, definitely, and backed by forceful policies, production control has the best sort of basis upon which to build.

The Master Schedule. The master schedule is a direct outgrowth of the general plan. It serves to allocate the available productive capacities to existing orders as far ahead as is practical. Based on estimates, which are either general or, if possible, made up from standard production rates, and dealing in terms of orders or in terms of main classes of product, the master schedule is the first place where the quantity or "how much" element is coordinated with the time element. It is the first expression of a plan of what to do, in what quantity and when to do it. It usually stipulates finished dates only, taking no cognizance of departmental time or operation time, although sometimes it can be broadly broken down and can designate finished dates required in each department, or at various stages, as a general guide.

It is in reality the first command resulting from the general plan. It commands the completion of an order or group of orders, or a given quantity of certain products, by a definite date, basing this command on known productive capacities. It is also a forecast of expected orders or anticipated commands, which later will become actual. It stipulates sequence as a general guide to further planning, although, as a rule, this is the sequence of the required finished date and not the starting date. The sequence of the starting date of orders needed to comply with the required finished date may be utterly different. The varying time in process for different products, different units, and perhaps different quantities governs the starting date plan.

One thing which is important is that every single order, no matter how small, should be given a definite place on the master schedule. Only too often what are considered too insignificant or too small orders are omitted, and this immediately minimizes the value of the master schedule, for often the cumulative effect of small orders is very large.

The disturbance coming from the interpolation of unscheduled small orders in the regular flow of production is often so great and far reaching that the entire schedule becomes worthless and undependable. An addition to the extra cost of production due to unexpected interruptions and planned changes is often so great that it absorbs the possible profits to be derived from the small orders, consequently every single order, every single lot, should be included in the schedule.

If the production is for stock, the stock orders covering each product indicating the quantity, and the date needed, should always take into consideration two very important factors, the economical lots and the profitable turn over of the whole inventory. Through the proper layout of the master

schedule, these two factors can be properly handled, in fact it is here they should be cared for.

It is important that the master schedule be so designed that it is flexible and that it can be changed and adjusted easily. It may be changed often, and under present day hand to mouth purchasing these changes will be more numerous than ever. These changes originate from either (a) the receipt of desirable new orders which must be given preferred position on the schedule, or (b) the necessity to set back or set forward orders on hand in order to satisfy demands of customers, or (c) unavoidable breakdowns in the manufacturing facilities setting back certain orders, or necessary revisions in the production estimates which may set back or set forward certain orders.

However, the fact that the master schedule will often be changed should never be an excuse for not making or using it. The more changes there are, the more difficult it is to control production without its aid, the more important it is carefully to lay out the work and preplan it so that these necessary changes can be provided for, and so that there will be as little dependence as possible upon memory and hasty judgment.

The Master Schedule should be kept in such condition at all times that it is possible to tell the effect of any additional demands on all the rest of the schedule. For instance, were the sales manager to have in mind the acceptance of an order which depended upon a delivery date in advance of the regular schedule, it is not enough to be able to ascertain if this one order can be produced on time. What is often more important is to know just which other orders will be affected by such addition to the schedule, and how much they will be affected. All the orders and their accomplishment must always be in mind. The production control staff will desire to cooperate with the sales department in accepting all orders possible and they should keep themselves informed so that they can give complete information as to the influence of any changes, and in that way give the sales department its choice. Only too many cases are seen where in the enthusiasm of the moment orders are accepted with the idea that, "We'll manage it somehow."

A good practice, which can be followed after having enough experience with a master schedule, is to allow a definite percentage for expected changes or for additional demands, when laying out the plan.

Forms for Records. The design of the master schedule which will make it sufficiently flexible and yet entirely practical, depends upon the individual case. The choice ranges all the way from the simple ruled sheet, through the different kinds of loose leaf sheets, card files, visible card and strip equipment, various graphic charts, up to the numerous designs of control boards, graphic and plain. No single design is best for all cases, but from among them a suitable type can be selected.

The choice is important. It is hopeless to try to schedule a complex production schedule without some type of easily read and quickly adjustable equipment. On the other hand it is a waste of time to use an elaborate production board to cover a simple production having very few changes.

Often after the master schedule has been laid out, together with a follow up, or "chasing" scheme, it is deemed to be complete production control.

In such cases no matter how well this has been done, it is really just a start; as the department, the machine and the operation must be controlled in order to get results.

Departmental Control

Departmental control requires:

- a. Breakdown of the production orders scheduled under the master schedule into shop orders, or departmental orders,
- b. Further breakdown of these into their various elements, including operations, machines, tools, jigs, fixtures, labor, materials, blue prints, and instructions,
- c. The preplanning of all these in a departmental schedule, somewhat like the master schedule, allocating the available facilities in such sequence that the finished date required for the entire order by the master schedule, will be met.
- d. Persistent follow up, constant adjustment, and continual coordination of all these elements so that the plan will be carried through.

Analysis of Operations. The analysis of operations is really a study of the individual operations necessary to produce the products called for on the shop orders, and needed in the manufacture of each integral part of every product. In many cases, where large quantities of a given product are made, standard operation sheets can be made showing the best methods, and routing the work in proper sequence. Such sheets are usually provided by the production engineer, and show the standard production rates required for the performance of each operation. Where these are provided the work of planning is much simplified.

Where production is not so standardised, the operation analysis must be made for each separate product on the order. This requires a detailed knowledge of the available equipment and facilities, and a working knowledge of how each operation is performed. Usually the foreman should be consulted in laying out this plan of operation, for close cooperation is needed here.

Sometimes it is found that economies can be secured by slight changes in design which will not affect the quality or practicability of the product itself. This requires cooperation between the designing or engineering department, and the production control staff.

Sometimes this study of operations, which as a rule also requires the study of the material specifications, shows up opportunities for the economical substitution of materials, using either cheaper materials or materials which may be in stock in surplus quantities; or which if not cheaper, may be especially desirable to move. These should be pointed out by the production control staff.

With some experience, and with the cooperation of the manufacturing foremen and supervisors, the production control staff usually becomes adept in analyzing operations, and are ever alert to point out possible economies.

The layout of operations should finally include an estimate of the time needed for the performance of each operation, taken either from standard rates set with the aid of time study or from carefully made estimates.

Planning and Controlling Labor. With the operations analyzed and laid out in the departmental schedule, labor requirements can be computed and planned. To have enough and not too much labor available at the right time and in the right place, to assign this labor to those operations which will carry out the schedule as needed, to keep this labor fully employed—this is the aim of production control.

When there is no such control, a surplus of labor usually follows, first because the lack of exact information fosters the maintenance of a force large enough for emergency requirements; and second, with no systematic control to prevent delays and eliminate interruptions, stabilization is impossible.

With proper planning of labor, advance notice can be given the employment department or the foremen who are responsible for employment, giving them opportunity to secure the right kind and right number of workers. It is also necessary to develop in advance a daily labor schedule, assigning definite work to each man, for the use of the foremen in giving out work. In other cases, labor can be dispatched through a regularly organized dispatching plan, with dispatch stations located conveniently, where workers can come for instructions, thus relieving the foremen of this detail. Which plan is used depends upon the individual case, but some plan, for daily and even hourly assignment of work according to preplanned schedule, should be arranged for.

To care for absence, illness and other emergencies, flying squadrons are often arranged for, consisting of a group of versatile workers capable of substituting on all the operations. In many cases such a group is indispensable to the maintenance of the schedule.

So the planning of labor, assigning or dispatching it to each individual task, and then providing it with necessary materials, tools and instructions to prevent all delays and interruptions, is desirable (a) because it pays to do so (b), because it is necessary to carrying out the plan, and (c) because it keeps the workmen satisfied.

Planning and Controlling Material. We have seen that production control has definite relationship to, and influence upon, materials, and must concern itself with materials at specific stages in the production flow, if the control is to be effective. These can all be briefly summarised under four headings as follows:

1. From orders, or from material specifications where standardization permits, raw material requirements are accumulated in detail, combining quantities taken from many orders or material specification sheets, in order to facilitate purchase and secure better prices on large volumes. These material requirements are furnished to the purchasing department far enough in advance to allow time for both negotiations and delivery from sources of supply. Where raw material stores are maintained, these accumulated material requirements provide the basis for a check of inventories to make sure that necessary material is available, and to discover any prospective shortages regarding which the purchasing department can be notified and steps taken to supply these shortages. The production control's main interest, here, is to have the right kind and right quantity of material ready to start through the factory on time.

2. To secure minimum production costs and at the same time provide most frequent turnover of inventories, economical lots are calculated properly to start work through the factory.

3. To control flow of production, to eliminate delays and prevent congestion, and to hold down the inventory of work in process, production control next controls the movement of material through the factory, so that it is carried along according to the pre-planned sequence, so that its movement is orderly, rapid, bringing each lot to the right place at the right time.

4. From information on hand as to present and prospective business, the production control staff lays out all the raw material requirements and furnishes this information to the purchasing department in advance so that sufficient but not excessive inventories are carried, of the types and kinds of materials which will move quickly enough to accomplish the greatest turnover of this stock investment. Through the economical lot and the control of the movement of material in process, the total quantity of process inventory will be held to its proper levels. Throughout the entire planning, scheduling, and control, the inventory of finished products, needed to give adequate customer service and at the same time provide the best turnover of the finished product stock, is provided and maintained. In all this phase of the work it will be seen that the principle objective is the conservation of the company's investment in materials.

Controlling Equipment. It is now an axiom that idle equipment or excessive equipment is an item of expense which needs to be minimized. Fixed charges, if nothing else, indicate the value of machine time.

As regards equipment, production control has these objectives. It must plan and control the production (a) so that all equipment is used to its greatest capacity, (b) so that it is used on the classes of work which it can perform most economically, (c) so that the work is dispatched to each machine in such sequence that the planned performance will result and the schedule will be met, (d) so that it is properly supplied with material, and (e) so that the necessary labor is provided to operate it and keep it running.

This requires the careful matching of the capacities of each piece of equipment with the requirements of the established production schedule as laid out from the analysis of operations and taken from the standard routings if they are provided, or from current routings of work to be done. It requires also an instant knowledge of breakdowns so that necessary adjustments can be made.

The assignment of work to equipment is as a rule cared for through the dispatching of labor, although in some cases it is more practical to dispatch to the machine, making sure, of course, that the machine is fully manned.

Where an unbalanced schedule makes it impossible to use every piece of equipment on work which it is best suited to do, careful adjustments of the schedule should be made so that the greatest effective capacity of the machine is obtained.

Controlling Tools, Patterns, and Molds. In almost every industry certain tools, jigs, and fixtures are needed in the operations, either by labor or as an adjunct to equipment. Wherever these are required especially for the

execution of an order, they become the definite concern of production control, for they must be available at the right time. If they are purchased in stock quantities or are made elsewhere to special designs, production control should work closely on these requirements with the purchasing department just as it does on raw materials. Where this feature is so extensive that tool designing and tool making departments can be supported as a part of the company's regular operations, it is usually well for the production control to cover these departments just as it does all others, and plan and control these operations so as to make its control comprehensive.

Production control should also keep closely in touch with tool storage, making sure that special tools are returned to storage, kept in proper repair and in such condition that they will be promptly available when they are again needed. By keeping in touch with what is available, they may often see ways of using old tools and fixtures, perhaps with some minor and simple changes, instead of purchasing.

What has been said regarding tools applies likewise to patterns, models, and samples.

Plant Layout. A standard plant layout put on paper, or in some cases made up in models to scale, is desirable for many purposes. Production control should study such layouts carefully so as to be familiar with the path of travel of all production.

Economical Lots. The economical lot is that quantity which can be produced at the lowest unit cost, including both manufacturing cost and carrying charges.

Many variables influence the size of the manufacturing lot, among which the more important are:

- Tool quantity required.
- Cost of set-up and preparation.
- Material cost per unit.
- Labor cost per unit.
- Overhead cost per unit.
- Space charges for storage.
- Interest rate on invested capital.
- Obsolescence.
- Deterioration in storage.

Attempts have been made to write a formula that includes most of these factors. The result is interesting as an exercise in mathematics, but is too cumbersome for every day use. It is possible, however, to obtain a simple formula of practical value for any given manufacturing plant, by eliminating the factors which are unimportant in that particular set-up.

The simplified formula can be expressed graphically, so that the results can be read directly from the chart, without computation.

Production Standards. Wherever standard production rates, made by job standardisation, exist for use in wage payment or costing, they can also be used for production control, since it must have available for purposes of planning some estimates of what to expect from actual performance.

Where such rates have not been established, it is often possible to use the estimates which have been established for estimating and quoting prices.

This has the advantages, that if the plan is based upon the estimated rates established in the price, and control is applied and accomplishes the plan, the expected profit will result.

Relationship of Production Control to Other Functions

Production control has some relation to nearly every other function in the organization. It draws from some divisions the information it needs; it controls the operations of others; it carries out the plans of still others; it furnishes information to some; while it cooperates with still others to accomplish certain results; or it may have all five relations to a few. Its more important relations are to general management, sales, purchasing, engineering, and cost accounting.

General Management. Basing its entire production plan on the company's general plan, which in turn is taken to express the company's policies, production control aims to carry out the general policies of the company as they pertain to production. It may logically be considered one of the principal mechanisms of general management in getting desired results.

In addition it maintains records which can be supplied general management to guide it in some of its important decisions and to aid in its judgment of results of other functions.

To a degree at least, it is unique in that it is a coordinating influence. For while it has definite work to do itself, it must bring together the accomplishment of various other functions and combine them for the common good. In this regard it also serves the interests of general management.

It should be an aid to general management in making decisions as to the expansion of productive capacities, the purchase of new machines, and in making capital investments having to do with production.

Sales. From sales plans and sales quotas, production control secures its information as to customers requirements, and uses this to establish its objectives. In many cases it receives orders and instructions from the sales division. In making its plan, it endeavors to carry out the desires of the sales division as to customers service so far as is practicable.

It provides advance notice to sales of unavoidable exceptions to the desired customer service, thus cooperating to maintain company goodwill. It cooperates in arranging for special service where this will add to such prestige.

It warns sales when costly demands are being made, or when such special demands will interfere with service to other customers or the general plan. It supplies sales with prompt information as to the status of various orders to help sales satisfactorily to answer customers' inquiries.

Purchasing. It usually supplies purchasing with information as to raw material requirements, planning far enough in advance to allow time for purchase and delivery. It cooperates with purchasing in holding down the company's investment in inventories. It cooperates with purchasing in moving materials and in eliminating material wastes.

Engineering. From engineering it secures information as to design, what to make, what materials to use, the material specification, and what quality standards are to be maintained. This is known as product engineer-

ing. Also from engineering it secures information as to operations, needed, standards, routing, sequence of operations, plant layout and standard production rates. This is what is known as the production engineering branch.

It must keep in close contact with engineering to secure all this information in time to accomplish the desired plan. In some organizations, it may even plan and control the activities of the engineering division, just as it does production. In every case it needs to have a definite understanding with engineering as to when drawings, specifications, designs and all the necessary information will be ready. For these are usually the foundations of the whole plan, and any delay will hold up the entire schedule all along the line.

Cost Accounting. Where standard costs have been established, production control aids cost accounting in the attainment of these standards by basing its plan on such standards and then exercising the control necessary to accomplish the plan. Thus in a larger sense, since standard costs constitute the cost accounting divisions plan, production control endeavors to carry it out. Next it assists cost accounting in measuring the discrepancies between the standard and actual performance and points out errors in the standards.

Where there are no standard costs, production control cooperates with cost accounting in collecting cost information, supplying it with records of results and in turn receiving from it certain data.

In all cases there must be a fine sense of cooperation between these two divisions. They use many identical records and should aim to eliminate all duplication and extra paper work by each amplifying its own records to supply the needs of the other, where this is practical, and in all cases by prompt release of records one to the other. These two divisions have much in common; there are many places where they meet and in fact many places where they can overlap. Therefore, there is room for petty jealousies and self centered competition. However, only ill advised individuals will forget that, after all, they are both working for a common result and that this result is the important thing. A little intelligent give and take will soon smooth out any rough places on the road which these two divisions may be traveling.

Relation of Production Control to Shipping. The above are the broad relationships to the major functions in the organization. In addition production control has some very definite relations to what may be termed subordinate functions. Important among these is shipping.

In many cases shipping is sharply separated from production, and production control is expected to control operations only up to the door of the shipping department. Even in such cases, there should be a close relationship, and production control should supply shipping with as much advance information as possible so that the latter can arrange to plan its work based upon the volume which is expected from production.

In other cases, shipping has become more complex, involving extensive shipping floors, storage rooms, and much handling. It is usually found advisable to have all of this planned and controlled by production control, thus extending the control up to the point where the product is placed upon the common carrier.

Relation of Production Control to Inspection. One other function with which production control has much to do is inspection. It must realize of course that inspection, so important in maintaining quality standards, must in no way be influenced by the requirements of the production schedule and will through the rejection of substandard product often interfere with the accomplishment of the plan. Production control will have to accept this and become reconciled to it, but it can also arrange to work so closely with inspection that it will know of such rejections promptly and make the necessary provision to replace them.

It is often possible to make allowances, dictated by experience, by a percentage added to the quantities put through, to cover expected rejections by inspection, and thus have left approximately the net amount desired.

The Production Control Staff

Often, when the installation of production control is contemplated, these questions are asked: To whom is it most logical to assign the work of production control? From whence shall we collect the production control staff? The answers must necessarily vary with the conditions in each organization.

Much of the work, many of the details, all of the planning in one way or another, and in fact about everything which is to be done by production control, has been going on, and has been done by someone previous to its introduction as a definite separate function. It may not have been done as intelligently, because of the lack of certain information; it will hardly ever have been done as effectively when not concentrated; nor will it have had the influence it must have to get the fullest results until it coordinates all the factors. But just the same, much of it has been going on, many of the motions had to be gone through. There almost always exists in the organization a certain individual, if not several, who have had most of the necessary experience for this work. It may be an assistant superintendent, one of the better foremen, an order clerk, a production engineer, one of the cost men, or one of many others. Qualities most essential to the success of this work are, familiarity with the office routine of the business, with all of the manufacturing facilities of the company, with the product and with the personnel of the organization. The other outstanding requirement is the ability to work tactfully with everybody in the organization from the chief executive to the last laborer, and to gain their cooperation. These qualifications are generally found within the existing organization and should be used where possible.

With someone chosen to head the staff, it will be found as the work is started, that production control will begin to undertake some of the details of other sections and offices. As the work in these other sections can be rearranged, it is often found that clerks can be released from those sections, and transferred to the production control staff, and in time that staff will have been organized.

Where the organization in existence is weak in talent, undermanned, or where the transition must be made as quickly as possible, talent from outside

will have to be selected and trained to do the work. Usually, by carefully introducing the work step by step, by arranging and rearranging the various details of the routine throughout the organization, it is possible to build up the staff, as well as the head of the production control division, from the existing organization. It may sometimes be advisable to use the experienced members of the organization in the production control, and replace them temporarily from the outside with new personnel, until such time as final adjustment of all the work can be arranged. Whatever else is done, if production control is undertaken, its effectiveness should never be lessened by the use of incompetent personnel or by attempting it with too little help. If it is desirable at all, it is usually so desirable that it can be made to pay its way. It can never prove itself, unless it is well and fully organized.

Cost of Production Control. Much of the work involved in production control was going on previous to its introduction, divided among many, and experience has shown that a rearrangement of the work merely transfers some of the personnel from other sections to the production control staff. Production control undertakes many of the details previously handled by the foremen and other supervisors and in time it is often seen that either the foremen can cover larger forces thus reducing the number needed or some assistants, clerical or otherwise, can be dispensed with. In either case the result is a reduction in the cost of this supervision which will go far to balance the expense of the production control staff.

It should not be expected that such results can be secured overnight, for there is a period of transition when some investment will have to be made.

Forms and Systems

It may appear odd to the reader that thus far so little mention has been made of the forms and systems of production control. This omission is intentional.

First, because all the space already used would not be sufficient to cover a discussion of this topic alone. The systems and the forms needed will vary greatly with the individual cases, as to the number, their design and type, their execution and their use. There are hundreds of forms, each of which has been effective in its particular use, but none of which could be recommended for all purposes. While general types of forms can be standardised, the individual forms themselves seldom can be. It follows that the system and the forms needed for production control must therefore be separately and specially designed and laid out for each different installation.

Second, since forms and systems are really just the mechanisms and tools through which the underlying principles of the work will be carried out, it seems advisable to emphasise fundamentals rather than the mechanisms and tools for unless the former are understood and complied with, the latter will secure only limited results.

To do this, it is well to approach the problem much in the same general manner as one would approach the construction of a railroad, first making a survey of the path over which the routine must travel, at which points various information will be collected, to what destination it is to be carried

and where it will be used; then laying out the sequence of this routine, indicating when it will be needed and when it must be ready to supply this need. Finally selecting the equipment, or in other words the forms and methods best suited to carry this information over the route so that it will be ready at the right time.

This specifically involves a knowledge of:

1. What information is desired.
2. The source of the information.
3. The route over which this information must travel for its collection and use until it is finally filed away.
4. Who will use it, and where it will be used.
5. When it must be available.
6. The relative importance of this information, as regards use, promptness, accuracy and descriptive detail wanted.

With these features in mind the necessary forms and method can be selected or specially designed. Sample forms may be used for guidance and the more experience the designer has the more immediate and effective will be the result and the less experimentation will follow.

These essentials must be kept in mind:

1. Simplicity is a virtue. Only as much and no more than is absolutely needed should be provided. Each new form or method must prove its value. Extra, miscellaneous forms, or miscellaneous columns in forms, only lead to confusion and require extra effort. There must be a definite purpose and use for every item.

2. Forms should be designed so that they require a minimum of effort in their use. This can be facilitated by the arrangement of the form, the use of colors in paper and printing, etc.

3. Forms must not be expected to cover too much. Sometimes very ingenious designs have defeated their own purpose, because they were too complex for the speed and facility with which the information must be collected, and also for ease in the use of the data.

4. The movement of the routine should always be forward. Retracing steps in the system usually causes confusion, delays, duplication of effort, and general ineffectiveness.

5. The system should be designed so that it is not "over the heads" of the personnel who must be depended upon for its execution and use. For instance, it is foolish to expect laborers moving materials to fill out complicated forms and reports. And schedules and dispatching forms must be so simple, definite and to the point that they will neither be misunderstood, nor require the application of unusual intelligence.

6. Duplication must be watched for. What will serve two purposes must, as far as is practical, be made to do so. Good routing of the information and prompt use and clearance to the next point of use will do much to facilitate this. Carbon copies and their prompt distribution will also help.

7. Above all, what should be kept in mind is that the use of the information is paramount.

To summarize, the system must be especially designed for each case, using past experience, and a complete knowledge of the basic principles of the production control plan which is to be applied.

Graphics. To cover the subject of graphics in proper detail would require a separate volume. It can only be pointed out here, as simply as possible, that perhaps in no other single division in business management can graphics be applied to such a degree of usefulness, as in production control.

Graphs have for their chief objective the quick visualization of many details, the emphasis on particular points of information, and the facilitation of the study of comparatives. Graphics are to business information what illustrations are to the newspaper.

The type and kind of graphics to be used should be especially designed. There is a wide variety to select from, and some will do the job better than others. Wide experience with the whole field of graphics is therefore to be desired in the person who is to develop production control.

Such matters as the general plan, the master schedule, the departmental plan, the dispatching of labor, machines and operations, the movement of materials, the route of the work, the machine down time for various reasons, the general fulfillment of the schedule, the keeping of delivery promises, the volume of work ahead, by departments, by machines and in total, all comparison of performance with standards and with the plan—all these and other items can be shown in graphics or in combinations of graphic arrangements with tabulations.

Symbolization. Symbolization is to descriptive business data what shorthand is to letter writing. It saves time both in recording information and in using it. These symbols may be numbers, letters, decimals, abbreviations, or descriptive combinations of letters such as the mnemonic code.

Some type of symbolization is a valuable tool in production control. Such things as plants and buildings, departments, workmen, machines, operations, types of materials, products, product parts and subassemblies, paths of travel—all these and others can be symbolized and should be wherever advisable.

Application of Production Control to Various Classes of Industry

Classification of Industries. Obviously, it is impossible to discuss in detail the many variations in business and their influence upon the application of production control.

However, industries may be broadly classified as follows to show the variation in application of production control:

1. Continuous processing.
2. Repetitive manufacture.
3. Made-to-order manufacture.
4. Jobbing manufacture.
5. Engineering manufacture.
6. Construction and building.
7. Standing-order manufacture.
8. Warehousing and shipping.

Each of these classes will be described separately with an indication of those phases of production control that are of greatest importance to each class.

Continuous Processing. Under continuous processing are found those businesses which convert raw materials, usually in crude condition, into one or a few products, putting them through a series of connected machinery and operations. These include paper making, cloth making, and weaving, chemical and related industries, milling of grains, steel manufacture, etc.

Production control, in such businesses, concerns itself first, with the maintenance and repair division, controlling this department and all its operations, so that it will function effectively and economically in keeping the wheels turning. It will analyze the work to be done, establish the standard gangs required for emergencies and consider how they can be kept occupied during intervals between breakdowns. It will control the supplies, parts, and tools needed, so that without too large an investment in spare parts, those needed are available in emergencies. It will consider which of these parts can be made on the premises, using the spare time of the mechanics who are kept available for breakdowns. Second, production control will arrange for and schedule the check-up of the product as it goes through the various stages of the process, making sure that the product is passing each one according to specification. Finally, production control will plan carefully in advance to keep the expensive units working steadily on what is needed most; will see that raw materials are available as required; will calculate the economical lot and will control the finished goods inventory.

Repetitive Manufacture. Repetitive manufacture represents a large portion of standard products, made in large quantities to relatively few different designs and sizes, and usually for stock. Our American tendency to mass production of standard articles has been steadily increasing the number which can be included under this group until now we find most daily necessities made in this way.

All phases of production control are valuable with this class of industry. Material, its quantity, progress and movement; the economical lot; the raw material requirements; the finished goods inventory; labor, its schedule and assignment; equipment, its maintenance, assignment and use; supplies, parts and tools, their consumption and requirements; these and all the usual features already discussed in detail are involved and should be preplanned and controlled.

Production control will arrange for and schedule the check up of the product as it goes through the various stages of the process, to be sure that it is made according to specifications.

Made-to-order Manufacture. The made-to-order group is the next stage away from repetitive operations and differs from repetitive manufacture principally in the fact that the product is made specially to fill orders rather than for stock. This group includes specialties of every kind, parts or subassemblies which go to make up other products, and the variations occur in the sizes, designs, and quantities to be made rather than in the kind of product, materials used, and operations.

Production control concerns itself first with the careful preplanning of the orders in the manufacturing schedule, working back from the required delivery dates. Having a large number of orders and separate lots requires careful analysis of the operations necessary for each lot and a close check-

up of the work in process as there is less opportunity for the processes themselves to set the pace and carry the work through.

Emphasis should be placed upon the raw material stock control, avoiding those small quantities of surplus material which will move slowly or not at all.

Jobbing Manufacture. Jobbing manufacture is where, within certain limitations, almost anything will be made. The limitations consist usually of the kind of material which is to be used. In this group are included some foundries, machine shops, carpenter shops, etc.

As with the made-to-order manufacture, production control concerns itself first with the careful preplanning of the orders in the manufacturing schedule, working back from the required delivery dates of the orders. Again careful analysis of the operations and a close check-up of work in process is necessary.

Blue prints, material specifications, tools, patterns, models should be as closely controlled as the operations and delivery dates. Raw material control is of less importance than in the made-to-order manufacture as material may be purchased partly according to orders.

Production control should further concern itself with controlling and scheduling labor and machines, as the possibility of idle labor and equipment is greater here than in the other classes of manufacture.

Engineering Manufacture. Engineering manufacture includes the building of special purpose machinery, specially designed equipment, bridges, and other large construction according to engineering specifications.

This type of manufacture has many of the characteristics of the made-to-order class, and all of those of the jobbing group. The engineering specifications, blue prints, patterns, tools, and models are of first importance in production planning.

Materials and the work in process should be controlled to such an extent that no delays will occur when assembling.

Construction and Building. While construction and building can scarcely be called manufacturing, it is included here, because it has many of the same problems and characteristics as engineering manufacture and therefore production control can be advantageously applied.

Production planning is concerned with engineering specifications and their completion within a predetermined time. The preparation of necessary equipment, labor forces and material is of equal importance but depends upon the completion of the engineering specifications.

Standing-order Manufacture. Standing-order manufacture may be any one of the other classes of manufacture, and differs only in that the sales problem is partly solved for some time to come.

The type of production control will depend upon which class of manufacture is involved. In addition, particular attention should be given to the customer's demands, both present and future. Raw material and inventories should conform to these requirements.

Warehousing and Shipping. While warehousing and shipping is not manufacturing, many of the factors of production control apply.

Production control will concern itself principally with inventories and office routine. The method of handling orders should be carefully planned as

time may be of great importance. The handling of merchandise through the warehouse into the car or truck and the routing to the consumer are of equal importance.

The Small Shop. From what has gone before, it may have been inferred that only the large plant and large shop devoted to mass production can be placed under production control. Just as there are misconceptions about the kind of industries and type of functions which can be covered, so are there also misconceptions about the size of shops which should be controlled. The statement is so often heard, "That's all right for a big plant, but this one is too small."

It should be pointed out that, no matter how small the business is, if it is big enough to operate as a business at all, it is big enough to use and respond to production control. It will require some selling, some bookkeeping, some purchasing, some superintendence and there is certainly no reason to believe that it does not also require some planning and control.

It must not be understood that this means the same amount of detail or that the plan needs to be in any sense elaborate. Just as every application of production control must be made to fit the difference in the types of businesses, so must it also be made to fit the difference in size.

When we analyze a small shop we find that it has the same problems, nearly all of the same elements and usually just as many different opportunities for losses and waste as the larger one of the same type. The first consideration should be to eliminate those which have become so small that they are negligible. This will at once simplify the whole matter. What will be left are the real essentials and these should and can be brought under simple control.

Usually these will include some kind of simple order system, an analysis of operations, and a production rate, which in the small shop is so often neglected. It is possible to use the time estimates which were made as a basis for price quotations, for the production rate, as has been recommended in the foregoing. With orders entered, operations analyzed and production rates established, a simple schedule assigning orders or operations to men and machines, can be made up and should by all means be followed. With this available the foreman can usually assign or dispatch the jobs; and finally a periodical check of actual performance throughout the day, against the schedule is an excellent follow-up not only of the orders, but also of the effectiveness of labor. With the orders available and the regular schedule made up, materials needed can be ascertained and purchased in time. Here material control is often especially important because with fewer orders in the shop, delays for materials assume large proportions, in many cases necessitating a shut down and therefore loss of a considerable part of the plant capacity.

Production control in the small shop does not presuppose a large staff of clerks. Eliminating the negligible elements and concentrating upon the main essentials only, usually the time, or even part time, of one person will suffice. An office man may combine this with other work, or a shop foreman may do all of it himself. However, if it is done, it should be definitely organized and carried out.

It should not be assumed that the system for the small shop need be elaborate or complicated. A simple routine can be developed. Many

forms needed in the larger plant are unnecessary here. A single form can, in many cases, be made to do multiple duty, and the few forms that are used can be quite simple.

Summary of Possible Results. Throughout this discussion, the various results which can and should be secured from proper production control have been mentioned. It might be interesting to summarize them now in a single list. They are as follows:

1. Reducing material inventories, and thus the cost of maintaining stocks, which is seldom less than 20 per cent of the investment and often as much as 25 per cent.
2. Balancing finished goods inventories, which helps to accomplish No. 1 and also facilitates customer service.
3. Holding down work in process, which helps to accomplish No. 1 and also aids in using plant facilities to fullest possible capacities.
4. Increasing material turnover, which also helps to reduce the cost of maintaining material inventories and improves the financial position of the company.
5. Using plant space, equipment and facilities to fullest possible capacity, which holds down capital investment and secures greater earnings on that already invested.
6. Holding down investment in tools, jigs, and fixtures, which does the same as No. 5.
7. Assisting labor in attaining and maintaining production standard rates, which may run from 10 per cent to as much as 50 per cent saving in labor costs.
8. Helping to meet standard costs, which is also a real dollar saving.
9. Aiding in the reduction of overhead, another dollar saving.
10. Meeting delivery promises.
11. Helping to maintain sales quotas.
12. Preventing overproduction.
13. Helping in executive control.
14. Aiding factory supervision.
15. Assisting labor towards greater earnings.

These are the fifteen major results which should be and can be secured through production control. The first nine can be classified as direct, tangible, dollar returns. The remaining six in the group are indirect and intangible, but although they cannot be accurately measured nevertheless are known to have a monetary value.

CHAPTER VIII

MOTION STUDY¹

BY LILLIAN M. GILBRETH, *President, Gilbreth, Inc.*

Motion study has sometimes been looked upon as a management technique, a method of measuring work methods by micromotion devices or cyclograph devices. As a matter of fact motion study is a philosophy of work, an attitude of mind, a method of stating, analysing, and solving work problems, as well as a technique of measurement.

As a philosophy, motion study is interested in looking for causes of effectiveness in work. It asks exactly what is to be done, who is the best person to do it, where should it be done, in what length of time, and by what method—the old *what, who, where, when, and how*. It thinks of man as the center of activity and as expressing himself in motions, aided by tools and machines, and using materials as a medium of expression. Production is the result of this expression. It can in a way be measured by the amount of product, but it is always measured also by the amount of skill it indicates and the satisfactions it arouses. There is a distinct change from the older idea that the product is of prime importance, and that the machine, tools and men are chosen with no other thought in mind than to make the most of the desired product of the prescribed quality at the least cost of materials, time and labor. The factors of the result are the same perhaps, *i.e.*, materials, machines, and men, but the emphasis is in the reverse order, *i.e.*, men, machines, materials. The philosophy of motion study says, "Study your man, determine what product he can best make, give him the working conditions, machines and materials that are best suited to him for the work, and you may expect success."

Motion Mindedness. As an attitude of mind, motion study looks at work as a combination of productive or efficient motions. The man who has this attitude becomes "motion minded." When he visualizes a piece of work he sees it in terms of the motions with which it should be done. He thinks of the worker as making these motions, and of the necessary modifications of what he regards as the ideal set of motions for doing the work, to suit the individual characteristics of the worker, physical, mental and emotional.

¹ EDITOR'S NOTE. The principles of motion study are discussed in this chapter with special reference to their application to the micromotion method of job study. The same principles are recognized as underlying effective use of stop watch methods. For a detailed description of their application to stop-watch technique see "Job Standardisation," by Charles N. Underwood and Charles W. Lytle, The Ronald Press Company, 1931.

The worker is tall; he is short; he has long arms, or legs; he is strong; he is weak. Every variation in physique affects his motion equipment. The same thing is true of variations in his mental make up. He is well educated or he is not. He has the requisite trade skills or he has not. He has been trained to use effective motions or he has not. So also, in the emotional field, he is excitable or calm; controlled or uncontrolled. There are countless other variations in all three fields that must be kept in mind in adapting the standard to his use. The motion-minded man has all these things in mind, but he visualizes and keeps clearly before him the "one best way" of doing the job, from the motion standpoint, and measures the necessary deviations constantly from the norm.

It is necessary to keep the motion study philosophy and attitude of mind before one, if one is to value its method of stating a problem and its technique properly. If these two are not carried through, with the philosophy and the attitude of mind motivating, the results can never be satisfactory. One can find the shortest motions of doing a piece of work, the motions least wasteful of energy, the quickest motions, etc. but he cannot find the *best* motions unless he remembers that they are to follow the standard or "one best way," given the best available worker, working conditions, materials, and tools, but always with allowance for individual skills and satisfactions.

The study of times is with us a by-product of motion study which uses the stop watch as one of its measuring devices. It records times as a part of its measurement technique. The old controversy between the stop-watch technique and the micromotion technique is so much a thing of the past that only students of management history are much interested in it today. The modern management man wants to know how he can most effectively discover and standardize the best work methods. We turn now to this.

Determining Need for Motion Study. The first step in making a motion study is to determine whether or not it needs to be made. "Is it necessary?" is always the thing to ask. Often it is not. In many cases a careful observation of the piece of work to be studied will show that it does not need to be done at all. Take for example a project to study the prepositioning of a subassembly, to be used in a final assembly. Consideration of the problem may bring to light the fact that the subassembly comes from another plant, perhaps another industry, and can perfectly well be packed and delivered to the plant where the assembly is to be done, so prepositioned that it can be assembled with the least number and most effective motions. This will do away with any necessity of the study in the assembly plant, and may mean practically no study in the plant where the subassembly has been done.

If the work suggested as worthy of study proves necessary, the next thing is to state the problem clearly and in detail, so that one can determine how much motion study is necessary and the time, effort and money that the study justifies. What does one expect the results of the study to be, and how reasonable are his expectations? What are the possible savings? The probable savings? The assured savings? What will these cost, in time of investigation, in cost of materials, tools, and skilled and unskilled

labor? Will there be by-products as well as products, and what will these be worth? What is the expected lag between the time of starting the work, of discovering the best method, of teaching it to a selected operator? Should all who do the work use the method? What about setting rates? What about maintenance?

If the assured savings are assured, the probable savings appreciable, the possible savings large, the conditions for a study are ideal. Considerable cost is justified if there will be by-products as well as products and if the time lag between the study and the returns is short.

How can one predict all these things? The expert motion-study analyst can do a surprising job. The beginner naturally cannot, but there are certain things that will help him. He can examine the work to find out if he can see a better way to do it, just by careful scrutiny. Often the fresh eye will discover savings that the accustomed eye has missed. It is well to develop ways of giving the jaded accustomed eye a new slant, by looking at the work from another angle, thinking of it as consisting of *motions* and not of *making something*. Even the handicapped non-visualizer can do this in time.

Much can be learned by asking questions. How many workers are to do the work? Will a few do it for a long time? Will many do it if only for a short time? Is it a job so nearly like other assured probable or possible jobs that results of studying it can readily be transferred to other jobs? An expert can also discover for himself or find out if it has elements of motions that are also elements of jobs which may seem unlike as wholes but which have identical elements. The *life* of the job must be known before one can tell what it justifies in study. Without this knowledge, many a poor beginner has undertaken a prolonged investigation and done a fine job at it, only to find out too late that "the model is to be changed" or that "this type is to be discontinued."

Characteristics of Motion-study Analyst. The above may indicate the type of person who should be chosen for motion-study work—a close observer, preferably a visualizer, one who has aptitudes for both analysis and synthesis, and who can see likenesses as well as differences; a careful painstaking worker who is intellectually honest, who knows how to measure and likes to do it—in other words a scientist. He should be one who likes teaching and is able and glad to learn the techniques; one who has a constructive imagination and is not afraid to use it. A stop-watch analyst may qualify if he is not set in his ways. There is nothing in his training that is a handicap and much that is a help, if he is open minded and can easily become motion minded.

This type, the open minded, find it easy to ask of any job, "What are the results that are to be accomplished? How are they being accomplished? Is there any simpler way of using the present method? Can I think of any way in which the same thing is being accomplished in any other field?" We shall have occasion to note later how analysis of the micromotion film and study of therbligs and simocharts teaches a man to transfer methods from widely diversified fields. The best motion study analysts often preclude the need for extended study of a piece of work by thinking of an entirely new way to do it, suggested by a likeness before unobserved, and making

such great savings that no further motion study is called for, at least at that time.

All Jobs Profit by Motion Study. There is practically no job that cannot profit by a detailed motion study, if one must not consider immediate and appreciable money savings. Often motion study at frequent intervals is warranted, because of improvement in materials, tools, or the type of men available for the work. We are considering all through this chapter the advisable procedure for production work, under typical industrial conditions where assured prompt and appreciable savings are considered an indispensable result of motion study. As a matter of fact, the training to be motion minded of everyone who takes part in or even sees a detailed motion study is always worth much more than the cost. So are the suggestions for improvement of the place where the work is done, and many other results. But this is not the place to discuss these.

The Motion-study Technique

Let us suppose that the decision has been made to undertake the motion study. What next? In many cases a record of the present practise of doing the work is necessary. This is especially the case where there is a likelihood of the motion study analyst being told, when he has completed his work and recommended a new method, that it is "practically what we have always done." If there is no danger of this, and obvious changes for the better are apparent, it is as well to make these before starting to make records. In any case, everyone who is to be concerned in the study should be told *why* it is to be made, *what* is to be done, and *what* the expected results are. If it is an early study in an organization, as many people as possible should be interested in it, and there is no surer way to arouse interest than to ask for cooperation; best of all, to insure that as many people as possible take part in making the study. It is well worth much time and effort in the planning to make this possible. It may cost more money if people are allowed to help, to watch what is going on, to make part of the records or to have what they do recorded, but this is certainly money well spent.

The Process Chart. The first aid in recording is the process chart. The work place may be photographed, or a drawing or diagram may be made, to accompany the process chart. On it the various steps through which the work passes should be carefully set down. This will probably mean studying all the workers in a process in order to be sure to set down any variation in the method used appreciable enough to be noted without a camera. The process chart technique is constantly developing, until now one is able to solve many motion-study problems through using only this, and none of the other measuring devices available. It often suggests desirable changes which result in such savings that it is advisable to turn to other problems and leave great refinements of study to some later time. Or if models change rapidly and there is a constant stream of small dissimilar orders the process chart may handle motion-study work very well, so long as new men do not have to be trained for the work. Training demands the use of all the techniques and the micro-motion film and cyclograph are indispensable. The process chart technique

makes it possible to break down the process into details, and an adequate set of symbols are available and act as thought detonators of things to observe

FIG. 1.—Process chart symbols.

(Fig. 1). But many organizations find it possible to accomplish what they need using only four of the symbols, that is recording only the *operation*, indicated by a large circle; *transportation*, or work moved by man, conveyo

truck, etc., indicated by a small circle; *permanent storage*, indicated by an equilateral triangle, with one of the angles down; and *temporary storage*, with a similar triangle, with another like it inside it. The two first symbols indicate among other things, *action* and the last two *delay* (Fig. 2).

The distance travelled may be indicated on the side of the chart. The chart may be elaborated to show *who* does the work as well as *what* is done. The work of the right hand and of the left hand may be charted side by side, to show what moves are made and when (in relation to the moves of the other hand), etc. So many new developments of the process chart are taking place at this time that it is only possible to illustrate by a long series of examples, which cover men, materials, machines, and motions. The motion-study analyst will usually use therblig symbols, which will be explained later in this article, on his process chart to keep the elements of the motions and possible economies in mind.

The process chart does not attempt to indicate time, though this might be done by adding stop watch or micromotion readings. But the recording of time is not their purpose. Motion study, since its beginning, has insisted that if the paths and speeds of motions were right, the times would be right also.

As for the field of application of process charts this is practically limitless. Not only the work methods of production, selling, office work, sports, etc., have been recorded but also the process of making a motion study and of attacking any type of problem. At present process charts are not only taking the place of long transcriptions of procedure, but such transcriptions already in use, many of them for years, are being put into process chart form, to save space and to assist in visualization. The charts enable one to see the details, in themselves, in relation to each other and to the whole.

When the process chart has been made, it is possible to determine what degree of detail study is necessary, and in many cases one circle of the chart will be broken down into a more extended study and this again expanded into a still more extended study.

Also possibility process charts may be made, as one thinks of improvements, and the saving in distance of transportation of elimination or delay indicated. Often it is possible from these to calculate the expense of the changes suggested and to decide whether these changes shall be made, without use of any other technique. Such changes may even lead to the design of a machine to do the work.

The Micromotion Method. It is when exact motions and the times of these are needed, or when the study of elements of motions would be profitable

FIG. 2.

that the micromotion method is used as a supplement to the process chart method of making motion studies. A study of the process chart makes apparent where a supplementary study would be of use. Very much the same standards of determining this are used as in determining where a process chart would be valuable. What is the life of the job? How many people are to do it, and what are the likenesses to other jobs? Added to this is the need to make minute savings, to have data as to time and motion paths, and to analyze these into therbligs or elements of motion cycles.

Just as the making of process charts has a highly educative value so has the making of a micromotion film. The procedure of making such a film is even more interesting to the participants. There was in the early days some question as to the cost, and often a hesitation to invest money in the equipment and the film, as well as to invest the necessary time for training and the time used in making the study. The stop watch was supposed to be by far the cheaper method. It may be well to discuss the relative advantages of the stop-watch method and the micromotion method here.

Micromotion or Stop Watch. Where times are needed at once, and it is better to sacrifice accuracy rather than to wait to take, develop and analyze a film, the stop watch is indicated. All motion-study analysts use a stop watch and become expert enough to do a rush job. Where the job is a short time job involving few people, has not many elements of motions which will be directly serviceable, and there are no micromotion records of similar jobs to use for estimating times and no motion-study trained analysts to help with the times, the stop watch is indicated. Where there is no need of a record of motions but only such a record of the work method as can be put into words the stop watch is allowable. But if a record of the motions is needed, if exact times are needed, if a simultaneous record of the motions and the times is needed, if a record that will be more accurate than the report of any number of pairs of trained eyes, always complete, easily available, readily understood, and comparable with other similar records is needed, the micromotion method should be used.

As for the cost, in these days no one needs to be told that motion picture cameras are available, cheap, adequate for the demands made upon them and undemanding of expertness in their users; or that film is cheap and the development of the films, the making of positives and replicas, handled entirely by the makers of the film. The pioneers had to search for, adapt, or design their cameras to be adequate recording devices for micromotion needs. Today any one can take a motion picture film and anyone can learn to take a micromotion film.

Who Should Be Filmed. Micromotion technique means first of all the selection of what is to be filmed. This we have discussed. Next it means selecting *who* is to be filmed. It is best to decide at once that every one doing the work will be filmed, though in most cases only a few feet of film need be taken, and this not for the value of the record as much as to get the cooperation in the study of every one on the job.

The best workers in the group should be selected for detailed filming. Motion study never tries to locate the "average man" or the "median worker" at this stage of the study. It is interested in recording the motions

of every worker who does excellent work, in order to be sure that every good motion cycle, no matter who makes it, is recorded on the film. The good workers are found by observation, by study of any available work records, by consulting the management and the workers themselves, and by adding to the group the "laziest" ones, who often have developed efficient methods of few motions and no unnecessary fatigue, and make high production with little exertion. One learns to see that efficient workers are likely to arrange their work places so that they get most done; use few head motions; follow more or less unconsciously the laws of motion economy and show indications of skills and satisfactions. For example, the eye of the skilled worker is always ahead of his hand in the motion cycle.

Choice of Film. It was customary in former days to use the large film, because of the sharpness of the record. Now the 16 mm. film is so good, and its use simplifies so much the weight, bulkiness and cost of the equipment that it is used in most cases for this work. The fact that one need not provide for developing, printing, etc., is also of course an excellent reason for its use.

The Microchronometer. A motion-study film is not a micromotion study without the use in the picture, of the fast-moving timepiece, or microchronometer. This records time to the one two-thousandth of a minute, and its use makes it possible to record not only motion cycles and their times but the therbligs, or elements of motion cycles and their times. As yet microchronometers are not on the market, because it is felt that such a timepiece without the training to use it for micromotion study, is worse than useless. It would only tempt its user to feel that he has a real micro-motion study, which he could not have without the technique and knowledge to make the film useful when completed.

Preparation for Filming. As with any photograph, the work place and worker must be adequately lighted; the work process within the scope of the lens, the danger of glare, etc., eliminated. The clock must be so placed as to be in the field of the picture, yet not interfere with the worker's motions or distract his attention. He must have the whole procedure explained to him, so that he will not be startled or confused, or otherwise prevented from doing his best work, and he must be interested in what is going on, the attempt to have his finest possibilities recorded.

All this is much simpler than it used to be. Lighting is no longer a serious problem, since portable, inexpensive, efficient globes, attachable to the ordinary electric outlets are available. No more is there need for flash lights or startling arc lamps, nor need to offer eye shades to the apprehensive worker, nor danger of the lights getting temperamental or the men who are handling them nervous, at the most inopportune moment. Where feasible the worker is placed against a cross-sectioned background; the work place is cross-sectioned, so is the floor; everything possible is done to put indications of space in the photographic record. It is scarcely advisable to describe here the methods and devices that make it possible to get a third dimension in the record. It is enough to say that any demands for refinements can be met by the established technique. As a matter of fact production needs demand very little besides a good motion picture with the fast moving clock in the picture, such as can be made by a motion-minded, motion-trained

analyst after a short intensive course of training. The refinements are needed in the research laboratory, and their use will result ultimately in an accumulation of data that will make the taking of films unnecessary for jobs having elements of motions already studied and recorded. Any one interested can master methods and devices and include in his records information which may not be needed at the time, but which costs little effort to acquire and which may be of great use to research later on.

Attitude of Workers. The worker should understand not only *why* the film is taken but also that he is supposed to do his best work. If he can also understand exactly *how* the mechanisms record what he is doing, before the actual filming is done, he will be able to concentrate better. A little time spent on explaining the mechanism of the apparatus will pay well for itself. Women workers usually object to being filmed without a chance to "clean up," and will do a better job if given an opportunity to prepare for the camera. But one should be careful to explain that a motion-study film is primarily a photograph of a method, not of certain persons, and that the method cannot be recorded if the worker wears restricting, dangling, or unworkman-like clothes. No one wants to be conspicuous. This usually handles the situation.

There has been little or no objection to the timepiece. The worker is told that times are incidental and primarily to be used as aids for comparison and selection of therbligs. He knows that the purpose is to discover the one best way, or standard, not to secure a time and motion record to be prescribed with no allowances, group or individual. He is usually in the spirit of a contest, and anxious to beat not only the past record of others but his own.

How Much to Record. The amount of film to be used must be determined by the nature and value of the study; the number of people to be filmed; the success of the undertaking as it goes on, any new variations of method which may develop under recording conditions, etc. Film is cheap; it is much better to use too much than too little. The scope of the process to be filmed should have been determined before the filming was started. The approximate amount of film that will be needed, if the operation is to be recorded fully, can be determined before actually starting to record, by use of a stop watch or an ordinary watch or clock. In many cases one will find, while doing this observing, that some preceding operation is essential to knowing the "get ready" and some succeeding, for the "clean up" of the "do it" which one is studying, and these should be included in the filming. On the other hand, often one finds that not all of the process chosen is significant enough to require filming. This means that one can stop the camera at certain parts, allowing the clock to go on, and start it again when there is need of a record. There is danger that one will stop too soon or start too late to record needed motion cycles, and if one is inexperienced, it is far better to record too much than too little. One should remember the footage used by the commercial motion-picture studios to make a picture and should not grudge a little extra film. Above all one should not neglect to film everyone, no matter how poor the method, who expresses a desire to be filmed. One should include a few feet of the work room, with the group being studied at

work and the motion-study group at their work, and end the film with a few feet showing the combined groups filing before the camera. This should insure that every one will have a chance to see himself in the picture. It may not be necessary to do this after the taking of micromotion films has become a part of shop and laboratory routine, but it is necessary during any study where the group concerned is unacquainted with micromotion study. Sometimes one gets information from unexpected sources. The less efficient workers occasionally have motion cycles or therbligs that are better than those of the best workers. Their motions if not good may be used as a base line from which to draw an efficiency curve. And material not of use to derive the best method is sometimes useful in teaching, or showing the wrong and the right way, or the much sought after "before and after" illustrations.

When the film has been developed and is available it should be projected for the recording group, and studied as a piece of filming and as a micromotion record. Any defects of film, focus, lighting, etc., should be noted. The film should then be shown to the group who were recorded, and their reactions to it noted. It is often possible to get valuable suggestions as to betterment of method from a discussion at this point.

The Simo Chart. Every frame of the film that contains data that might be valuable in determining the standard method of doing the work should be studied next and the data transferred to a simultaneous motion cycle chart.

The "simo chart" is a record of the motions and times recorded on the film. It is made on standard cross-sectioned paper, a large roll being used, which is placed in a specially designed desk, which permits an adequate working area to be in place before the analyst, while he looks at the film through the small aperture where it is illuminated and magnified. His row of colored pencils for recording the therbligs is above the paper, each with its therblig symbol over it, all in the usual sequence and positioned for ease of use.

At the top of the chart is pasted the legend and the printed strip listing the parts of the body, left arm, right arm, etc., each with subdivisions making it possible to record down to the finest of finger motions, eye motions, etc. The times are recorded down the left side of the chart, as the work progresses. Every worker who has been recorded has his motions analysed upon a separate chart, the identical technique being used on each. If, for example, the hand motions are broken down into finger motions in one case, they should be in all cases.

Making a simo chart calls for the greatest care and accuracy, and in many cases for judgment and experience. If one is the least uncertain of the therblig, or cannot decide where one therblig ends and another begins, a question mark should be added to the chart at that point in order that one can return to it for reexamination or submit it to a group for expert attention. Often the picture of some later therblig of the same kind or some other cycle will clear up the matter. Then one can return and better the record. It is not necessary and often is not advisable to make a complete or beautiful chart when taking off data on the preliminary chart. This can be done later, when one has finished the first draft, or assigned it to a specialist in chart

making. An added advantage is that one is more reconciled to scribbling on the right side of the chart any suggestions that one receives from the film as to causes of delays or of inefficiency, or any suggestions as to betterments.

SYMBOL	NAME OF SYMBOL	SYMBOL COLOR	NAME OF COLOR	NAME AND NUMBER OF PENCIL
	SEARCH		BLACK	DIXON BLACK #331
	FIND		GRAY	GRAY #352½
	SELECT		LIGHT GRAY	#352½ APPLIED LIGHTLY
	GRASP		LAKE RED	LAKE RED #321½
	TRANSPORT LOADED		GREEN	GREEN #354
	POSITION		BLUE	BLUE #350
	ASSEMBLE		VIOLET	VIOLET #323
	USE		PURPLE	PURPLE #323½
	DISASSEMBLE		LIGHT VIOLET	VIOLET #323 APPLIED LIGHTLY
	INSPECT		BURNT OCHRE	BURNT OCHRE. #335½
	PRE POSITION		SKY BLUE	SKY BLUE #320
	RELEASE LOAD		CARMINE RED	CARMINE RED #321
	TRANSPORT EMPTY		OLIVE GREEN	OLIVE GREEN #325
	REST FOR OVERCOMING FATIGUE		ORANGE	RUBEN'S CRAYOLA ORANGE DIXON ORANGE #324
	UNAVOIDABLE DELAY		YELLOW OCHRE	YELLOW OCHRE #324½
	AVOIDABLE DELAY		LEMON YELLOW	LEMON YELLOW #353½
	PLAN		BROWN	BROWN #343

FIG. 3.—Standard colors for therbligs.

It is difficult to "spoil" a beautiful chart by adding such notes, yet they are often the most valuable part of it, from the standpoint of bettering existing methods. We have seen a motion-study analyst stop charting and run out

into the plant, to make a change in a work place or in routing that was the key to the saving for which the study was primarily made.

The making of simo charts is by far the most protracted and exacting work so far described. Every novice is surprised at the footage of charts from a film, especially if it is a clear record. Many a good-looking picture is not a good record. The clock is obscured, or some part of the body is in shadow and it is not possible to record the therbligs.

The Therbligs. These therbligs should perhaps be listed here. There are seventeen so far. If there are more they will come by dividing the ones now discovered or by finding that the sum of the seventeen does not make up a complete motion cycle. This latter was the case with the discovery of the therblig "plan," the last to be listed. The operation is divided into motion cycles, as has been said. The motion cycle is not divided into motions as it is almost always difficult and often impossible to find the beginning or the end of a motion. The motion cycle is divided into elements of the cycle called therbligs, a coined word, because no adequate word was available. These are (see Fig. 3):

1. Search.
2. Find.
3. Select.
4. Grasp.
5. Transport loaded.
6. Position.
7. Assemble.
8. Use.
9. Disassemble.
10. Inspect.
11. Preposition.
12. Release Load.
13. Transport empty.
14. Rest for overcoming fatigue.
15. Unavoidable delay.
16. Avoidable delay.
17. Plan.

Certain of these therbligs are much easier to identify and separate from the rest than are others. For example, "grasp" is usually easy to identify and to bound, while "search" "find," and "select" are often so blended as to be difficult or impossible to separate; in which case all three symbols may be used.

If teaching is the prime purpose of the study and immediate results are desirable from the savings standpoint, the person from whose work the chart is made should be shown the results as soon as possible. In any case his comments, as soon as he understands the technique are almost certain to be of value. The film should always be ready to show with the chart, so that any point not clear or discussable may be illustrated by the original film record.

A simo chart should be prepared from the film of each worker recorded. When these are completed they are hung side by side, so that one can compare

the therbligs. Every slightest deviation in the therblig and in the time of the therblig is noted, and a tentative standard method is built up by synthesizing the best therbligs from all the charts. It is very seldom the case that the derived method lies in the consecutive motion cycles of any one worker. Usually the synthesis consists of a therblig from one chart or a motion cycle, if it is specially efficient worker, then one from another. The completed chart contains the best practice of each of the group of workers studied combined into a work method.

The *standard method* must, as nearly as possible, use the *rules for motion economy and efficiency* which are as follows:

1. Both hands should preferably begin their therbligs simultaneously.
2. Both hands should preferably complete their therbligs at same instant.
3. Both hands should not be idle at same instant, except during rest periods.
4. Each of the seventeen subdivisions on various kinds of works has a proper range of elapsed time in which it should be performed. While this differs for different people, correct standard from which to deviate should be established.
5. Motions of arms should be in opposite and symmetrical directions, instead of in same direction, and made simultaneously.
6. Hesitation must be analyzed and studied, and its cause accounted for and, if possible, eliminated.
7. Shortest time demonstrated in one part of study should be used as a mark to attain, and reason for other times required in other parts should be known.
8. Number of therbligs required to do work should be counted for one best way is almost always sequence of fewest therbligs.
9. Best sequence of therbligs in any one kind of work is useful as suggesting best sequence of other kinds of work.
10. Every instance where delay occurs, suggests advisability of providing some optional work that will permit utilizing time of delay if so desired, or making fatigue study of interval.
11. Variations of time required for any single therblig should be arrayed and causes recorded.
12. Lateness of various parts of anatomy as compared with other portions should be recorded.
13. Since fast motions cannot be made in same path as slow motions, learner will acquire desirable automaticity quickest if he works at motion speed of expert from beginning, regardless of quality of resulting work.
14. Lateness of anatomical members of expert should be observed most carefully. Where it is not possible to work from first at speed of expert, this lateness should be copied as closely as possible.
15. Rhythm is most important, and is largely a matter of time and not of distance, although making a motion covering same distance many times consecutively will affect rhythm to some extent.
16. Awkwardness, grace, ambidexterity, and bimanuability, are all greatly affected by time element, which affects also hesitation and decision and many other psychological variables.

The motion-study analyst has these laws in mind when making the synthesis, and is governed by them when making his choice of therbligs and therblig sequences.

Arrangement of the Work Place. All through the motion study he has had in mind three other things. The first is the *height of the working surface*, which will make work motions easier and less fatiguing. This height is calculated from the height of the elbow standing, when the arm is relaxed. The work surface should be of that height which will enable the worker to keep the arm in a restful relaxed position all through the work. A chair should be provided which keeps the elbow at the same relative height when the worker is seated, and should be provided with casters, so that the worker can reach for it with his foot, without needing to turn the head, and thus not be interrupted in his work.

The second thought that the motion-study analyst has in mind is that of the *circular work space*. If the worker extends his right arm forward to a normal reach and makes a sweep across the work place from left to right and right to left across his body he will have covered the most convenient zone for work with the right hand. In the same way, if the worker extends his left arm out and makes similar sweeps, he will have covered the most convenient work area for the left hand. The overlapping area in front of the body will be the most convenient area for two-handed work. (Fig. 4.)

FIG. 4.

The third thought of the motion-study analyst is that it is efficient to *have things to be used by the worker in the two-handed work space*, if they are not in the way there, or so arranged that they will be most easily available at that place. This includes positioning of tools, materials, and handles of machines, and routing to and from the work place, everything that means motions conforming to the rules of effective work, all through the time that the work is going on.

Changing the Work Place. There is a variation of opinion as to when it is advisable to make the changes necessary to carry out these three principles of motion and fatigue economy. Sometimes it may seem advisable to make the indicated changes in the work place before making the process chart, sometimes before making the film. Usually it is evident that the best time to make them is when the simo chart is being studied to standardise the methods, because often a film suggests an entirely new set-up. It is

thinkable that this may necessitate making another film; usually not. Sometimes it is necessary to make jigs or fixtures; usually it is necessary to make or adapt bins. Often conveyors of one sort or another are indicated. These are designed always with the thought of making the most efficient motions possible, and easy, and least fatiguing.

Use of Micromotion Study. It is always advisable to keep the film in a form that corresponds to the charts. In some cases illustrative frames are printed from the film on paper and pasted to the simo chart, to assist in the visualization of what is being prescribed. Often paper strips and frames are prepared for record books and filing cards. These tend to motion economy in locating motion cycles or interesting therblig data. It may be advisable to reedit the film at this point making a special print for teaching, which contains only the efficient work elements.

The work of the micromotion-study analyst is not done until the best worker has been taught the motions of the standard method and is able to do the work by the prescribed method in the predicted time. When this has been done the data are handed over to the training department and to the task and rate setting departments for incorporation into standards to be used and taught. These techniques will not be described here. Motion study does not prescribe allowances to be made, nor the type of wages to be used. It confines itself to determining and teaching the method. The great advantage of using its data from which to calculate shop-work standards is that the allowances and deviations made are from an accurately derived norm. In case of mistakes or dissatisfaction, it is always possible to return to the norm and go on from there, correcting. Again, the film presents an accurate record not only of the method used but of the worker who used it. In permitting minute changes of method to compensate for individual weak points to utilize individual strong points, one can always compare the worker recorded with the one assigned to the work, and check on the necessity for such allowances.

The micromotion-study film is a wonderful training device. It helps the learner to visualize. It permits of repetition at the prescribed intervals for an efficient learning process. It can be accompanied by a lecture. It can serve as a guide for motor learning if the learner is told to follow the motions of the worker recorded with his own arms, hands, etc. It makes clear not only what is best, but why, illustrates paths and speeds of motions, simultaneous motions, etc. It is an always available, infinitely patient teacher.

The Cyclegraph. It is possible to project the film on a cross-sectioned background and trace with a pencil the path of a motion in two dimensions, and thus to supplement the film's inability to record a motion path so that the record remains after the frames that contain it have passed the shutter. The cyclegraph technique, the third technique of motion study to be described in this chapter, was invented to meet this need and to add the possibility of recording the motion path in three dimensions and in time.

The cyclegraph is made by attaching a minute electric light bulb to the hand, finger, or other moving part of the worker, and photographing, preferably with a stereoscopic camera, the path of the light as it moves through space. Through the introduction of a timed interrupter, it is possible to

make chronocyclegraphs which show the path of the motion, the time, the direction, the speed, and if several moving parts are to be recorded, also relative speed. The cyclegraph technique, highly developed to meet every need, has been neglected during the past few years but both need for and interest in it has been lately apparent, and it is being revived and adapted to the need. It has proved itself the outstanding device for recording skills and as the new studies in skills and satisfactions, as related to motions, are carried on, we may expect to see greater and greater use of the cyclegraph technique.

Aims and Results of Motion Study. Motion study, fatigue study, and skill study, from their beginnings recognized as closely related, are increasingly being felt as *one* problem. If production is to insist on the efficient expenditure of effort, plus skill, resulting in the desired product, plus satisfaction to the worker, motion study and its allied fatigue and skill studies are plainly indicated. Those who use them wisely will eliminate waste, both material waste and drudgery and fatigue, and will themselves find opportunities to exercise skills and enjoy satisfactions, in the procedure as well as in handling the results. Best of all will be the outcome to the workers, who invariably enjoy being studied and participating in the studies. Better motions, less fatigue, greater skills and satisfactions, these are the aims and the results of motion study, in its broadest interpretation, and unless these are enjoyed by the workers we shall not have succeeded in doing our job.

CHAPTER IX

INCENTIVES AND SUPPLEMENTARY WAGE PAYMENTS

INCENTIVE PLANS FOR DIRECT AND INDIRECT LABOR

BY KENNETH B. ANDERSEN, *Member of the Staff, American Management Association*

Need for Incentives. After the amount of time that should be consumed in performing a given task is determined, either by time study, motion study, or estimate based on past experience, the next problem that arises is the method of inducing employees to exert the effort required to accomplish the work within a period equal to or less than the time established. The fact that an incentive is needed to secure the desired effort was recognized by early students of man's behavior. Darwin, for instance, observed that men differ much less in their mental abilities than in their zeal and determination to make the most of themselves, and later William James concluded that all moderately healthy men who live on the lower planes of activity can greatly enlarge their accomplishments by an act of will; by tapping hidden reservoirs of energy and putting them to work. Similar observations are made constantly by production executives who have the opportunity of comparing employees' efforts before and after incentives are applied.

Kinds of Incentives. To stimulate the desired response, we may appeal to one or several of the forces that regulate man's behavior. The desire for material gain, fear, pride, rivalry, and loyalty can be aroused, each by different appeals, and in each case the response of the worker may be affected to a very marked degree. Whatever medium management may employ to arouse these mainsprings directing human action is, in the wider sense of the term, an incentive. The desire for material gain, for example, may be stimulated by wage payments in excess of those paid to the worker on a time wage, prizes, stock bonuses, wage increase, or promotions, while fear may be aroused by a second group made up of penalties, lower wages, demotion, and separation. This second group of incentives may be regarded as negative appeals to the acquisitive tendencies and even though directly opposite in character to positive appeals, classified as financial incentives.

In our consideration of financial incentives we are interested, therefore, in any effort of management to influence the response of the worker by systematic or arbitrary adjustments in total earnings. The relationship between response and amount of earnings may be very direct as it is in the case of piece work and incentive wage plans or the time lapse between cause and effect may be of considerable duration resulting in the more indirect relation-

ship usually existing in annual bonuses, increases in time rates or promotions where the response may not affect earnings until six months or a year or more has elapsed. To be a truly financial incentive the adjustments in earnings should be systematically prearranged and directly dependent upon the response of the operator or group to which he belongs. Wherever possible, wage plans used by modern management are based on the premise that the maximum continued response of the employee can be secured by combining forms of direct and indirect financial incentives with those that are non-financial and appeal only to his loyalty, rivalry, pride, or sense of superiority.

Purposes of Incentives. In attempting to describe more definitely what is meant by the response of the operator we can also answer the question, "What are the different purposes for which incentives are used." Ordinarily, in thinking of response, the first element that occurs to us is the quantity produced. That, in actual practice, however, means number of units completed that are satisfactory in respect to quality, so the most important elements in response are usually accepted as being both quantity and quality. Most of the incentives found in industry are intended to increase the effort of the worker in these two directions, the majority being based primarily on quantity with a requirement that quality be satisfactory before the unit produced is counted as complete. There may be a gamut between good and bad divided into several quality grades making it desirable to establish a distinct incentive for the operators to concentrate the quantity produced in the highest quality grades. In this case, separate quality incentives can be supplementary to the quantity incentive. Other elements in employee response often considered sufficiently important to warrant some form of financial incentive are avoidance of waste in use of materials, attendance, punctuality, regard for safety, suggestions for improvements, and reduction of normal learning period. Any one of these factors may be subjected to some form of measurement which will enable management to set up systematic financial incentives in order to stimulate a more satisfactory degree of response from labor.

Measuring Response. The response of the directly productive operator has been measured with the least difficulty and it is in this field, therefore, that financial incentives in the form of wages are the most common. This is especially true in industries manufacturing standardized products on a large quantity basis. Where labor is highly specialized and motions largely repetitive, the problem of establishing an index or gauge which will measure response accurately is comparatively simple. Take for example the operator drilling the same size hole in identical pieces of steel, his output can be expressed by an index or number which is the sum of all the holes drilled. The number of holes that should be drilled within a given period of time can be established as a task and as long as we maintain all of the factors affecting the speed of his output in the same condition, we can place this task before him as the degree of response that he should attain. Management may then establish some form of wage plan in which remuneration is dependent to some extent or entirely on the measure of attainment.

Measuring Response Where Conditions Are Unstandardized. Difficulties arise, however, even in establishing a reliable index of response for all pro-

ductive operators, especially when the units of work in process are not standardized or there exists a variation in factors which affect very seriously the rate of production. The material on which labor is being applied may not run uniform, changes in temperature or humidity may affect progress, or management may be deficient in maintenance of flow of materials and in repair and set-up of machinery and other equipment used in performing the work. Variations of this kind are beyond the control of the operator, making it more difficult to arrive at an index of response which correctly gauges his effort. In spite of these obstacles wage incentives have been established in all kinds of industries and for all classes of productive workers, both skilled and unskilled. One large public-utility company in the Middle West measures output as a basis of wage payment to car-shop employees, construction crews, and even linemen.

Variety of Wage Plans. The wide application of wage incentives in all types of industries resulted in many modifications and additions to the original incentive plan of paying workers an agreed-upon amount for each unit produced, a method of payment that has been in existence longer than our present industrial system and still one of the most widely and most effectively used. Beginning with guarantees to piece rate operators that they would receive at least a given amount for an hour or day, the modification process has gone on until it is almost impossible to determine how many different wage-payment plans have been developed. The writer is familiar with one attempt that was made to classify the different plans in which a count of 200 was reached. Obviously many of these plans differed from others by only a few very minor details, and yet many of them have a distinct label. No wonder that the average production executive gives up in despair when plans are referred to by name only.

Limits of Variations in Plans. Methods of wage payment are limited on one side by a fixed time rate that remains constant regardless of the volume of production and on the other side, by forms of piece work which provide an increasing payment per unit, for all units produced, as production within a given period of time goes up. The high multiple piece rate is illustrated by a payment to the operator of 3 cents per piece when twenty-five units are produced in an hour, $3\frac{1}{2}$ cents per piece if thirty are completed in the same period and perhaps 4 cents when the rate of output reaches thirty-five. The changes in the amount paid per unit may be gradual with an intermediate rate between $3\frac{1}{2}$ and 4 cents, continuing with the above illustration, for each additional unit produced as production goes from thirty to thirty-five or the change in the amount paid per piece may take place in a single step, in which case the $3\frac{1}{2}$ cent-rate would continue in effect for the thirtieth up to and including the thirty-fourth unit. These steps or abrupt changes in rate per piece are found in many different plans including the Taylor differential piece rate and its modifications which came from Gantt and Merriek.¹

¹ The charts presented on the following pages are included for the benefit of those interested in the mathematical structure of the ten distinct forms of wage plans. They are also very helpful in understanding the classification of wage plans which follows.

Symbols used in the charts are:

E = earning in dollars.

Details of Wage Plans. Between the boundaries of fixed hourly or daily wages and high piece-rate plans there exists a large variety of curves and straight lines representing the mathematical bases of wage plans designed to meet all kinds of conditions. Often the claim to distinction is not the structure of the wage incentive but the accompanying records and graphic reports that are basically non-financial in their appeal, or tools that stimulate management to provide the operator with the cooperation and facilities that make a larger production possible.

Other plans are characterized by methods of measuring production in terms of output per minute instead of hour. All of these supplementary features are designed to make a more potent and conscious appeal to the employee and frequently they are very effective but they can be disregarded when the basic structures of incentive wage plans are being compared because they are not inherently part of any one plan and do not alter the earning arrangement.

Location of Task. Among the wage forms which guarantee a fixed time rate to the operator and then pay a supplementary wage based on the relationship between actual response and that established as the standard or task, we find some plans that pay no extra wage until the standard response has been reached while others start paying additional amounts at 62½, 66⅔, 70, and 75 per cent of task. This variation is due to a difference in the concept of what constitutes task. Some believe that the requirements should be set at a point that can be reached and exceeded by the normal worker, another group set standards on the assumption that 100 per cent should be attained by the most capable operators only, and with the introduction of micromotion study, a more solid foundation appears for a third group who regard the standard as an attainment of perfection never completely realized by any operator. Standards of the last type are rarely used. Obviously the incentive wage plan established and the attitude toward task are closely related for the more nearly task approaches the ideal response the more essential it becomes that our extra payments start at a point below task. The actual results of starting payment at 100 per cent and setting a high task would be practically no incentive. While the determination of standard response is a research problem, it should be based on a clearly defined policy of what constitutes task. If there is no common understanding of

N_p = number of pieces produced.

R_p = rate per piece in dollars.

R_h = rate per hour in dollars.

R_m = rate for machine in dollars.

H_d = hours per full day.

R_t = rate per time unit such as week, month, or year, in dollars.

H_a = hours actual.

H_s = hours standard for any given N_p .

B = bonus in percent of base-time wages.

The following charts are reproduced from Charles W. Lytle's "Wage Incentives for Direct Labor," *Mechanical Engineering*, p. 495, July, 1929.

Among the books on this subject, "Wage Incentive Methods" by Charles W. Lytle. The Ronald Press Company, 1929, is a very complete unbiased analysis of twenty-five widely used plans.

this concept among members of the shop methods department, we may find that the determination of task has taken on an individual administrative aspect and the setting of tasks has become a process of allowing the operator to make a certain estimated amount. The result is different types of tasks set up in various departments having the same wage plan and a consequent inequality in the earnings of workers in the same class.

Straight Time-payment Plans. Although management has a large variety of wage plans from which to select, it is possible to reduce this assortment to four basic earning patterns. First is the fixed hourly, daily, or weekly wage which remains the same regardless of fluctuations in production. Here it is apparent that all gains or losses resulting from changes in the worker's response accrue to the employer and there is little financial incentive for improvement. If no well developed non-financial incentives exist where this form of payment is followed, response is practically certain to be 60 per cent or less of the employee's actual capacity. This condition is changed completely with few alterations in method of payment by the introduction of individual production records and establishment of a definite task. A financial incentive is added by setting up labor grades with a gradation of time rates and clearly defined production qualification for each grade. The use of two fixed time rates with provisions that the higher rate shall be used when production is sustained at a certain level constitutes a relatively strong financial incentive.

Piece-rate Plans. The second class of wage-payment plans is based on the straight piece-rate method which in its original form did not include any minimum earning guarantee. As already explained, the first modification was the Manchester plan which retains the straight piece-rate feature and simply adds a guarantee that daily earnings will reach a minimum amount regardless of production. Taylor started with a straight piece-rate payment and introduced a definite task. When the rate of output equaled or exceeded this task the employee received a greater amount for all units produced. This means that there is a sharp increase in total earnings when task is reached and consequently a strong incentive to reach that point. The Merrick plan follows Taylor's by adding a third piece rate and reducing the difference between the first two, and Gantt provided for a guaranteed time rate until the operator could reach task, the point at which he shifts to a piece rate. Gantt also provided for an abrupt increase in earnings as the operator passes from the day guarantee to piece work.

Any piece rate plan which gives the operator one or more abrupt increases in the amount paid per unit as production increases is referred to as a differential or multiple piece-rate plan and the change in rate per piece is known as a "step." Different plans in this group have been developed from the use of a time wage guarantee and variations in the number of steps used, the amount of the step and the point at which it occurs. Taylor justified the payment of higher rates when production is increased by showing that only a small corresponding increase occurs in some indirect manufacturing costs and that no change takes place in others. As the units produced increases, the indirect costs are spread over a larger number of units and the unit cost of factory indirect expense is lowered, therefore, more than enough to offset

the increase in unit labor costs. The final result is a saving in total unit cost in spite of the larger portion going to the operator.

Gain-sharing Plans. In direct contrast to the multiple piece rate feature we find that the unifying characteristic of the third class of plans is a decrease in the increment per unit of output paid to direct labor as the degree of response is improved. The result is that as production increases the total wage of the operator goes up but he receives a diminishing payment per unit, so his earnings do not increase as fast as they would under a piece-rate plan. In most of the plans of this kind a minimum day rate or hourly wage is guaranteed. A standard task is set and any saving that the operator is able to effect by reducing the actual time required to complete the task is shared between him and the employer. Ordinarily, the gain sharing starts before actual response equals 100 per cent of a theoretical high task.

The plans belonging to this group vary chiefly in two respects, first in location of the production point relative to a high task at which gain sharing or premium starts and second in the portion of the saving paid to direct labor. The original Halsey plan, one of the plans in this classification which is widely used, provides that the saving in direct labor cost is to be divided equally between operator and employer. To the employee this means a fixed time wage and as his response goes above task an additional payment of one-half of an amount equivalent to a piece rate at task times the number of extra units produced. The employer's portion is sometimes subdivided and a large share paid to foremen and indirect labor. Another well known plan in this class is that of Bedaux who usually distributes three-fourths of the saving to the operator and the other fourth to supervision. The gain sharing principle is followed also in the plans of Diemer, Baum, Barth, Rowan, and Ficker, the first two incorporating step arrangements similar to those discussed under multiple piece-rate plans.

Empiric Plans. The remaining payment plans have been classified as empiric due to the fact that the incentive wage earnings are not based on a simple arithmetic pattern like piece work or gain sharing but increase according to a predetermined or empirically established scale as actual response approaches and goes beyond standard task. Fixed hourly wage rates are guaranteed and also serve as a basis for computing supplementary earnings. After the standard task has been set the actual response is compared with it and an index of efficiency is computed by finding what per cent of task the actual response represents. The percentage expressing the relationship between the standard and actual response is termed the per cent efficiency or bonus standing and for each gradation of this percentage a corresponding figure appears in the bonus table informing the operator what per cent of his time earnings will be paid to him as a bonus. In the Emerson plan, for instance, the bonus table indicates that supplementary payments start at 67 per cent efficiency. Working at this pace the operator receives a small fraction of 1 per cent of his time wage. As response improves from 67 to 100 per cent, the bonus earnings rise from 0.01 to 20 per cent of the time rate and above task 1 per cent of the time wage is added for each additional per cent of efficiency. It should be noted, however, that in spite of this fact the earning curve does not provide a piece rate above task.

Employees may not have a clear understanding of an empiric plan but usually most of them can compute their efficiency standing and then by use of the bonus table determine their bonus earnings.

Several others in the empiric class including the Knoeppel plan provide bonus payments starting at 67 per cent of task. The Wennerlund earning curve above task provides a bonus equal to piece-rate earnings, thereby allocating to the direct producer the entire saving in direct labor costs. Others follow the gain-sharing principle. The portion of the saving going to the employer is very small, however, except under some of the Parkhurst plan schedules. Step provisions for abrupt increases in bonus earnings also occur in this group in the plans of Bigelow, Bigelow-Knoeppel, and Parkhurst.

Danger of Classifying Wage Plans. Before leaving the classification of wage plans it should be noted that any attempt of this kind in which specific plans are referred to by name cannot be accepted as entirely accurate because it deals only with original plans. During an installation and after its completion, changes and additions are sometimes so extensive that not only the superstructure but the mathematical basis of the plan as well is altered materially. In actual practice, therefore, we should not be surprised to find a variation existing under the same name that has strayed so far away from the original plan that it really belongs in a different class.

Uses of Straight Time Payment. Wage payments based on the single factor of time have practically no incentive value and can be used effectively for two kinds of work: first, when the work itself or conditions surrounding performance are so unstandardized that it is impractical or impossible to determine with any degree of accuracy the quality and quantity of response that should be accomplished during any given period of time; and, second, wherever management control is so highly organized that incentive wage plans are unnecessary. The variety and quantity of productive work which cannot profitably be measured in some way has been diminishing steadily in modern progressive companies and now constitutes not more than 10 to 15 per cent of total volume measured in terms of productive hours. The major portion of straight day work still originates in plants where modern methods have not been accepted or in companies whose entire efforts are expended in maintaining self-assurance that operations are unique and therefore unmeasurable. Quality of workmanship in these plants is not as a rule any better than in the company where financial incentives are balanced by sensible methods of quality control.

The payment of a fixed time rate to operators in large mass-production plants is increasing. Whenever goods in process move continuously from one operation to the next the standard task is set automatically by the amount of work assigned and the movement of the production line. No wage incentives based on degree of response are necessary since that must be the same for each individual. The operator must synchornize his output with the flow of production or fall out of line, an incentive strong enough to move any employee if the hourly rate is high. Inference should not be made, however, that all employees on a continuous line production will respond satisfactorily to a straight time payment. Conditions often exist which make an incentive wage plan far more desirable.

Advantages of Piece-rate Plans. The shifting to the employee of all risk of gain or loss resulting from fluctuations in production constitutes our strongest financial incentive. This is especially true if piece rates are increased in the higher ranges of production. The straight piece-rate plan is comparatively easy to operate, clerical costs are low, operators have little difficulty in understanding the mathematics of the plan, and it serves as an excellent basis for budgets and standard costs. But flexibility in payment of individual wages is lost and if there are a large number of separate rates, general wage adjustments become very involved. There is no opportunity to include extra compensation to individual operators for such intangibles as loyalty, cooperation, versatility, regularity, and care of equipment.

Some companies, like Westinghouse Electric and Manufacturing, have overcome this objection by establishing an individual rate to each operator for a standard hour output. Here the amount of work constituting a standard hour is the same for every one but the amount paid to each man for a standard hour may vary. This method may be used to add flexibility to any piece rate plan. The administration of the plan is merely changed to a standard hour basis and all piece-rates are set in terms of hours instead of dollars.

Advantages of Gain Sharing. Gain-sharing plans were intended primarily for use in conjunction with tasks set on the basis of past records and estimates. Although the incentive value of the plan decreases, as the share of saving withheld from the operator is increased, it is also true that his earnings do not fall off rapidly when production is lowered. When this is the result of a variation in some factor beyond the control of the employee, his sense of justice may respond more favorably than in the case of a piece-rate plan.

Representing a sharing plan to employees as a partnership with the employer may sound so altruistic that the skeptical recipient will be moved to do a little mathematical analyzing with a resulting substitution of disgust for skepticism, especially if he is working on similar repetitive units and has had previous piece work experience. It is believed that morale and response will be affected much more favorably by a sound truthful presentation of a plan of this kind than by any lofty idealistic sugar coatings. If an operator's production, for example, can be increased temporarily by an unusually good run of raw material, he will respond to a gain-sharing plan realizing that the increase is not due to his efforts alone and that a poor run experienced at a later date will not reduce his earnings in direct proportion to the reduction in production.

Advantages of Empiric Plans. Many of the gain sharing plans together with those in the empiric group require more clerical work to record quantities produced, actual time consumed and to compute total earnings. The production and accounting records can be made to pay a large share of their own way, however, by being designed so that copies may be returned to operating departments and there serve as effective non-financial incentives. A number of the plans requiring more involved computation appear intricate when first introduced to the employee and some of them are never thoroughly understood by everyone. If adequate bonus tables and records are supplied enabling the employee to compute total earnings and thereby make the customary check on the accuracy of pay-roll computations, excellent results

will be secured in spite of the fact that the derivation of the formulae or graphic presentation of the earning curve never attains a state of conscious existence in the thought processes leading to greater exertion.

Selection of Wage Incentive Plans. The problem arising from our analysis of plans is that of selection. Which plan will secure the maximum cooperation between labor and management in the reduction of total unit cost to a minimum in any given set of conditions? How many different plans does the plant require?

The original solution was to select one of the incentive plans, install it in every department if possible, and leave those who couldn't be included under a straight time wage. Two or three years after installation the same plan would be operating successfully in some departments and in others the observer would find few traces of an incentive wage or else modifications so drastic that relationship with the original was extremely obscure. Plants with a combination of large scale and job order production were very apt to have this experience.

In other instances incentive plans which were not designed for the existing conditions have been used successfully for a considerable period before their inadequacies became apparent. This temporary success was due to the ease with which some savings in labor costs could be secured if no financial incentives existed prior to installation or much of the improvement was attributable to management controls, standardization of conditions, and non-financial incentives set up at the same time. Many large companies reached the point where employees' opposition to a plan became decidedly audible and management's objections numerous before real attempts at scientific selection were begun.

Number of Plans Needed. One of the first results of these studies was the increasing recognition of the fact that many large companies have such a large variety of operating conditions that a single incentive wage plan and a straight time wage plan require several or more modifications in order to insure the most effective response from operators in all departments. Further ramifications developed when it was found advisable to apply the same incentive plan to some operators as a group instead of placing them on an individual basis. It should also be noted that the profitable use of a number of wage plans is not confined to the larger companies. Single plants employing 500 or 600 employees or less often find that conditions also warrant the use of more than two wage plans.

Qualifications for Those Who Select. Selecting the wage incentive plan is an important assignment for someone in the organization who is familiar with the four classes of plans described and the distinctive features of the more common members of each group. This information can be secured from publications, consultants, and exchange of experience with other companies. Knowledge of internal conditions should be very extensive and should serve as a background for a broad understanding of the industrial relations, accounting and management aspects of the factors influencing selection. Finally an ability to evaluate the importance of each factor is required because all of the evidence will seldom indicate the superiority of any one plan and yet the number of wage incentive plans applied must be

reduced to a minimum in order to secure the lowest clerical and administrative costs.

Selecting the Elements of Response. The first analysis to be made prior to selection is concerned with the purpose of the incentive. How do we wish to use an incentive plan to reduce total unit cost? Our study begins with the three common elements of production, quantity, quality and consumption of materials. An attempt is made to determine to what extent the variations in these factors depends upon the human factor or fluctuations in the effort of the operator and to what extent these variations affect total unit cost. A careful analysis of itemized cost is the point of departure for the second step. The importance of each of these three elements varies considerably but usually for direct operators little time is required to find that quantity is the most important element, unless labor is being applied on very expensive raw material. Many times the identity of two elements merge and can be measured by a single index. Quality and quantity are combined most frequently and in some processes the relationship between quality and waste is very close. In the case of inspection and some forms of maintenance work we find that quantity is relatively unimportant and the operator's attention must center on quality. This procedure is undertaken, therefore, for the purpose of deciding what element in response shall receive the major emphasis and whether the wage incentive shall be based directly on a measurement of one element with those remaining left to other forms of control or whether supplementary incentive payments are to be set up for one or more of the remaining elements.

Factors Considered in Selecting Wage Plans. There are a large number of factors that will influence the selection of any type of wage plan after we have determined what elements of response are to serve as a direct basis for a financial incentive. In order to make the discussion clearer they are divided into three groups: labor factors, management factors, and cost factors. A few of the items in each group will be considered from the viewpoint of how they influence selection.

Labor Factors. In considering labor's probable reaction to a plan, those responsible for the choice should be close enough to the man at the bench to understand exactly how his mind works and what his attitudes are. Does the average operator possess sufficient intelligence to understand how one of the more complicated empiric or multiple piece-rate plans operate and why they are equitable or would they respond more willingly to a simple piece rate? The history of previous forms of payment, and still more important, the wage plan in use immediately prior to the new installation serve as a background for the operator's attitude and consequently should be considered. Straight day-work operators will accept a gain-sharing plan or empiric plan whose earning curve does not ascend on a piece-rate basis and response will be comparatively high while operators accustomed to piece work will object immediately. If the labor supply is restricted, it may be necessary to guarantee a high hourly rate with additional response easily secured by a gain-sharing plan. A high rate of turnover means that the wage plan should encourage a steep learning curve. The effort required may be stimulated most effectively by little or no hourly guarantee but a differential

piece rate that provides a very rapid increase in earnings in the lower stages of production.

A healthy morale among operators can be injured seriously by the introduction of a straight piece-rate plan which ignores differences in the more intangible qualities of employees while an empiric plan based on a low hourly rate may be just as strong and yet avoid this danger. A form of piece-rate payment based on standard hours rather than units produced is better suited to group applications where productive efficiency is the same for each member but differences in skill and ability require recognition in individual earnings. Stated briefly, labor factors considered include intelligence, skill and training, past history, supply available, morale, and degree of cooperation necessary among employees.

Management Factors. Among the management factors most importance is given to the method of determining tasks. A high piece-rate earning curve that is suitable for tasks accurately and scientifically determined may be entirely unfit for departments where rates depend largely on good judgement and past experience. The operator's attitude, even where gain sharing plans are in operation, is still decidedly opposed to poorly set tasks or a management that permits the continued existence of improperly maintained equipment, unnecessary variations in raw materials, inadequate supply of small tools and indirect materials, delivery of work improperly processed in the preceding operation or any condition that in his opinion unnecessarily retards his rate of output. There is little respect for the management that uses a sharing plan in order to avoid correcting these conditions and ultimately operators will rebel and disregard the premium plan as calling for more effort than the extra payment is worth.

Application of piece-rate plans demands that conditions affecting the rate of output and effectiveness of operator's efforts must be even more carefully standardized. A scientific job study should serve as a foundation for the setting of rates which will be satisfactory to operator and management until methods are changed. The possibility of setting accurate rates becomes especially important when multiple piece rates or step plans are considered. Here earnings increase rapidly, indicating to the employee that the maximum response is desired. Securing this degree of response will be practically impossible if a few poorly established rates and the resulting excessive earnings necessitate rate adjustments. As soon as confidence in stability of rates is lost, response will not go beyond that earning point which is considered as a safe maximum. Even the man of exceptional ability will hold back on the job rather than run the risk of assuming responsibility for a cut in rates.

Factory budgets and standard costs operate most successfully in conjunction with wage plans that give constant labor costs per unit produced. Adjustments can be made, however, for other types of plans. Production control has already been mentioned as capable of so much refinement that straight time payment may be entirely satisfactory. Obviously our wage plan should blend with the method of planning, scheduling, and recording production for dispatching requirements. Some of those who have devised payment plans have included them as part of a complete method of produc-

tion control. In this case an installation usually includes the entire management plan.

Cost Factors. The investigation of cost factors is the basis for an intelligent answer to the question, How will the plan affect total unit cost? It is important here that we do not confuse total unit cost with unit labor cost which is often only a small part of the manufacturing cost. As the worker's response improves, unit labor cost is decreased by use of a straight time wage or gain-sharing plan, remains constant under straight piece work and increases when multiple piece rates and step features are used. But the highest level of response comes only when the last type of plan is applied. Consequently if indirect expense is proportionately high as compared to direct labor due to the use of valuable equipment and heavy items of fixed expense, total unit cost may be lower as a result of spreading the burden over a larger number of units produced in spite of the increased labor cost per unit. In a plant where several large automatic machines are operated by one employee, for example, a step plan may give the lowest total unit cost because it is the strongest incentive and stimulates a maximum number of operators to come up to task.

Some increase in overhead usually occurs with installation. Clerical expense, inspection costs, time study, and rate setting staff salaries and other increases in indirect items can be estimated and listed as charges that should be more than offset by savings. Care is essential at this point in order to avoid disconcerting criticism by a skeptical treasurer after the plan is operating. He may admit that the plan is fine and production has increased merely as a tactful prelude to directing attention to the large increase in indirect expense that has been responsible for the failure to reduce total unit cost.

Maximum savings will result only from a detailed evaluation of all the factors mentioned and a selection of the plan favored by those that weigh most heavily in the final manufacturing cost.

Installation of Wage Incentives. After a thorough method has been followed in selecting one of the existing wage plans or formulating a new modification, installation becomes a problem in salesmanship and training. Assuming that the difficult assignment of developing a reliable index of measurement and setting accurate tasks has been completed satisfactorily, the successful installation of the plan is a matter of tactful explanation to the operator of a method whereby higher earnings will be possible. To facilitate a high degree of response we must also provide the instructions and supervised training that will enable him to reach the higher ranges of the earning curve. Beginning with the highest official in the plant and ending with the departmental foreman or gang boss, the line officials should be given all the details of the plan before any attempt is made to explain it to any of their operators who are selected to inaugurate actual operations.

Clear and simple explanations with plenty of concrete examples showing typical wage computations are essential and should be given to the operator by a staff member rather than risk an incomplete description by a foreman who has just become acquainted with the plan. An individual application will progress smoothly if presented to one or several operators who are

intelligent and inclined to accept new ideas. Increased earnings soon arouse a receptive attitude in the whole department. When the installation has gone this far the plan can be tested for a period and necessary adjustments made before extension to other departments where further modifications may be required. Wherever a highly developed spirit of cooperation among operators is essential or desirable, the plan can be applied to operators on a group basis. Successful installation here depends to a large measure on selling the plan to the group leader and giving him a thorough understanding of his responsibilities, particularly his influence in determining the earnings of each individual by regulating the size of his group to correspond with the fluctuations in volume of work.

Maintaining Standard Conditions. Difficulties often arise after the plan is installed in maintaining the conditions regarded as standard at the time the task was set. This is a very definite responsibility falling to management and as soon as incidents begin to occur regularly which indicate to the operators that management is not viewing these responsibilities seriously, confidence and interest begin to wane. Machinery and equipment properly maintained, inspection requirements clearly outlined and allowed to remain unchanged, provision for adequate supply of small tools, materials, and indirect labor, these factors and others affecting output are given careful attention in plants where incentive wage plans are the most satisfactory.

For unusual conditions beyond the control of management, temporary adjustments in rates are sometimes made. This practice can easily become too common and result in changes and allowances being made for conditions which will soon be offset by some temporary advantage in the opposite direction. If no systematic control over indirect expense has been set up, more detailed attention to these items of departmental operating cost is recommended as a counteragent to the natural tendency to emphasize increased production at the expense of added costs elsewhere.

Addition of Non-financial Incentives. Regardless of the strength of the wage incentive plan, response is improved by the development of non-financial incentives. Individual production records posted in the department, departmental totals or standings advertised throughout the division or plant, graphic presentations of progress or comparisons of standard and actual performance, and provision for written explanations when operators fail to reach task are methods that have given excellent results when used in addition to the financial incentive. All extra earnings are given a more unmistakable identity when placed in a separate pay envelope or issued by separate check. And finally an occasional verbal recognition of outstanding performance by line and staff officials strikes a very responsive chord and yet requires so little effort that it is a habit worth cultivating.

Use of Consultants. Business service organizations provide valuable aid to the company whose personnel does not include anyone who has had previous training in incentive wage installations. Costly mistakes are often made, however, by clients who retain consultants and assume that they can come into a plant and set up a "system" that is complete and ready to be operated permanently by a person whose mental capacity is suited for routine activities only. It is the opinion of the writer that outside

service is most helpful in this connection when it is used primarily in an advisory capacity and as a means of training members of the organization whose ability to do original thinking has already been demonstrated. Men of this type can start the installation under constant guidance of the consultant who gives instructions in practical application of principles and, by reason of a wide experience, many helpful suggestions regarding modifications to meet unusual conditions. The less work actually performed by those from the outside, the better for those who are left to carry on through the years of installation. It is also certain that the efficient head of the shop methods department devoted to time study and wage incentives never succeeds in carrying his plant to such an advanced state of perfection that his activities can be described as routine.

Wage Incentives in Drafting, Tool, and Machine Departments. Recent discussions of incentive wage plans have devoted special attention to applications in tool rooms, machine and drafting departments. Usually the activities of the first two include a large amount of repair and replacement work as well as manufacture of new equipment. The difficulty in these departments has not been the application of the wage plan but the development of reliable indices for measuring response and establishing standard tasks to serve as a basis for the incentive plan. In the average-size plant these departments have little repetitive production if output is regarded in terms of complete dies, machine parts, or drawings. An analysis of all operations required to complete each unit or component part of the complete die or drawing, however, usually results in a catalogue of operations or fundamental elements that are largely repetitive in spite of slight variations in size, shape, and contour. Accurate time studies can be made for such elements and tables formulated for building up tasks for the completed unit.

Time elapsing before total earnings are computed often extends over a period of several weeks when a single rate for the completed job is given to the operator. A gain-sharing plan appears to be well suited for this class of work, but even here it is dangerous to generalize because instances are known where straight piece rates merely estimated by the foreman have been very effective in securing a high level of response from employees in a jobbing machine shop.

A financial incentive is just as necessary in these departments as in any of the others since observation and experience indicate that response under a straight time plan is no more likely to be above a 50 or 60 per cent level here than anywhere else. True the work is inherently better suited for holding the operator's interest, but the variations responsible for this fact also prevent the close supervision and control possible in repetitive production departments. Highly skilled operators are also tempted to drift into an attitude of smugness and security that is not especially conducive to maximum response.

Maintenance Departments and Other Indirect Labor. Maintenance department employees and other indirect labor offer a problem similar to the one in the drafting or tool room. Much of the indirect labor, however, is assigned to activities so repetitive that there is little difficulty in measuring response and determining tasks. Sweepers, power house and boiler room

operators, and window washers often fall in this class. Other indirect operators such as truckers and factory clerks are sometimes placed on an individual incentive basis or included with a number of productive operators in a group application. For those assigned to loading or unloading in the shipping and stores departments, individual response cannot be segregated but combined results are easily measured, thereby facilitating group applications.

The Factory Office. The last class of production division personnel to receive incentive wages has been the factory office employee. Individual or group applications have been set up for clerical workers and usually a payment, based on group results, to production planning, scheduling, and other staff departments where it has been possible to establish standards of accomplishment. And finally, after successfully selling all the others on financial incentives, the time-study department with a true spirit of gallantry has waited until last to declare that even it needed an occasional stimulus and thereupon, of its own volition, has made its bow and entered the incentive circle.

EXTRA FINANCIAL INCENTIVES FOR SUPERVISORS

By E. E. BRINKMAN, *Industrial Engineer, Holeproof Hosiery Company*

During the World War and the period immediately following it, financial incentives were frequently provided for foremen to increase production with little regard for the means employed in obtaining it. It appears to have been only recently that much progress has been made in the development of some of the more scientifically balanced incentives for supervisors. In the continuing war on waste in industry started a few years ago, industrial management has found it increasingly necessary to pay attention to the elimination of waste in every field of activity and in every feature of operation of each individual department of the business. As a result, supervisors have been provided with incentives to improve a number of conditions, such as:

1. Working efficiency.
2. Idle or lost time of all workers and machinery.
3. Repairs.
4. Scrap and waste.
5. Overhead costs, such as indirect labor, labor turnover, cost of supplies.

In comparison with the mass of literature available on other industrial management problems, very little has been written on methods used in stimulating supervisors to step forward and more completely assume their vital responsibility in the role of "the key men in industry." It shall be the object of this discussion to clarify the principles underlying the design and operation of well-balanced and effective incentives, to set forth a tentative summary of existing practices employed in the stimulation of supervisors and to illustrate some of the principles involved in the operation of financial incentives.

An accurate discussion of incentives for supervisors has also been found to be dependent upon a uniform definition of this term. Webster has ably defined incentive as "that which moves the mind or has a tendency to incite

to determination and action." In accordance with this definition, an incentive for supervisors can be defined as that systematic arrangement of manifesting recognition of achievement which moves to thinking and incites to action, those people directing the work of others. An incentive must therefore be systematic and definitely arranged. There must be a manifestation of recognition of good work in some tangible or intangible form that will use a man's self-interest as a handle in stimulating the supervisors. These incentives, in order to be effective, must therefore be designed to stimulate the suggestion of improvements in such a manner that they can be believed to be a possibility. If the incentive then also incites to action this same supervisor, the improvement suggested by his thinking will become a reality and a contribution to industrial efficiency. This is the fundamental object of incentives. Those arrangements that are often called incentives and are not designed to produce this mental effect and physical action are only useless hindrances to smooth operation of an industrial organization.

Classification of Incentive Plans for Supervisors. A recent analysis of existing practices among thirty-five representative concerns in twenty-one branches of American and Canadian industries brought out the fact that incentive plans for supervisors in use today can be classed according to their character as follows:

1. *Appeals to Inherent Motives Other Than the Desire for Money.* A number of such plans manifest a recognition of good work through the provision of special considerations, such as promotion, praise, publicity, prizes, and emblems or certificates of recognition. Most of the appeals to inherent motives have their roots in primary motives, such as self-preservation, taste, pride, and desire for approbation. Many employers can profitably make use of this type of incentive where none is being employed today. It can even be used where other types of incentives are in force.

2. *Grading and Salary Adjustment Plans.* This plan consists primarily of systematically evaluating the results of a supervisor's work and revising salaries in accordance with the results of this grading. The salary adjustment is universally accepted as a powerful incentive and has possibly a greater effect upon people higher up in the ranks of industrial organization. A consideration of incentives for supervisors would therefore be incomplete without the inclusion of the salary adjustment incentive, particularly if it is accompanied by systematic grading.

3. *Financial Incentives, Indirect Measurement.* Profit sharing, stock ownership, and annual bonus systems fall under this classification. The results of supervisors are, in these plans, measured indirectly, usually in the form of profits made from the year's operation. The measurement of results is necessarily indirect and is a composite of the results of the efforts of all supervisors and executives in the organization. The effectiveness of profit sharing has been shown to be in proportion to the rank of the people participating in the plan and inversely proportional to the size of the group participating.

Stock ownership is becoming prominent. Much thought and study is being applied to its successful application. The problems involved are numerous and it has been found that all business reaction and plans must be carefully weighed before their adoption, because ultimate effects are very

far reaching and have a definite effect upon the social structure of American industry.

Annual bonuses usually consist of an arbitrary bestowal of cash to supervisors deserving special recognition. This plan is probably in more general use than is usually known, because many of the bonuses are paid in an individual and personal manner by officials of corporations and proprietors of business organizations.

4. *Financial Incentives, Direct Measurement.* Incentives falling under this classification consist of premiums and bonuses computed and paid from results of operation in comparison with systematically or scientifically established standards. Results of operation usually include those factors and features of operation over which the supervisors as individuals or as a group have an opportunity to exercise control.

This type of incentive has apparently been given considerable application in its many varying forms. It also appears to have much difficulty in being uniformly well known and understood. This, however, is natural, because such plans do not lend themselves to general application and general discussion. The plans are usually designed to fit actually existing requirements in each individual company, and in each individual supervisor's job. Varying factors are employed for providing incentives on the features of operation which require attention from the supervisors.

The direct measurement of results and the payment of money for good work under this class of incentive plan makes necessary, an accurate and reliable method of either measurement, grading, or a combination of both.

Measuring. There are certain characteristics bearing upon the qualifications of a supervisor which may be definitely ascertained and measured. These characteristics concern mainly the tangible elements of his work. We can thus measure in definite units a man's attendance, the quantity and quality of production under his supervision, relative costs, and some other factors having to do with his performance and efficiency. Systematic recording of these tangible factors is what is meant by measuring.

Grading. There are important but less tangible characteristics which cannot be definitely measured. These characteristics include character, personality, leadership, capacity for development, and other items which must be judged mainly by opinion. These characteristics are included under the term grading.

An accurate and reliable system of collecting and recording data on the results of the operation are of primary importance when measurement is used. Cost accounting, for example, must be well established for the successful operation of a direct-measurement incentive plan, because the plan, in order to be effective, must produce definite results that mean savings to the company in order that the premium or bonus paid will have the desired effect upon the supervisors. The supervisor must feel that the premium he receives is a part of the savings he has effected. A systematic recording of the intangible characteristics is necessary for a direct grading financial incentive plan.

Factors Measured. Establishment of incentives based on direct measurement and grading requires an exhaustive study of the supervisor's job and

selection of the proper factors that are to be measured. What are the things the supervisor is to accomplish and how well can they be expected to be done? It is probable that most concerns employing this method of designing their foremen's incentives use different factors for supervisors in different departments because the factors that determine profitable operation of departments are different. This can be expected because a certain group of work is usually departmentized because it is different from other work in the same factory. The following summary of factors used as a basis for operating direct measurement financial incentives will act as a guide and suggestive table for the selection of factors in the design of incentive plans or for the improvement of existing plans.

- a. Efficiency of productive workers.
- b. Quality of output.
- c. Utilization of equipment and machinery.
- d. Amount of production.
- e. Elimination of waste materials.
- f. Non-productive or indirect labor costs
- g. General cost of operation.
- h. Development of short cut methods.
- i. Safety and accidents.
- j. Cost of supplies used.
- k. Operations on piece work.

Some companies using financial incentives of the direct measurement type base the entire bonus payment on one of these eleven factors; efficiency of productive workers or amount of production often serving as a base in cases of this kind. Others use from two to five of these factors in one and the same incentive plan. When several or more factors are used combinations of direct measurement and grading are frequently set up.

Individual and Group Applications. Does the foreman's plan operate separately or on a group basis? This question is being asked by many people considering the use of direct measurement financial incentives and much is said for and against the use of the separate incentive plan for each supervisor. It appears that both arrangements have their place because it is conceivable that there are cases where the work of one supervisor cannot be clearly identified from the results of the efforts of another and the employment of a group plan is inevitable. On the other hand, it is generally conceded that the pulling power of an incentive plan is greatest when one individual only is in the plan and decreases as the number of people in the group increases. Most companies, therefore, use a separate incentive plan for each supervisor wherever individual results can be definitely segregated without excessive clerical costs.

Making the Foremen's Incentive Effective. To secure the greatest degree of effectiveness it is important to select only factors that are directly under the supervision of the foreman and to place major emphasis on those accurately measured. The plan must have the whole-hearted support of management in the maintenance of standardized operating conditions. The cooperation of the shop methods staff is particularly desirable whenever the supervisor is attempting to make changes that he believes will result

in improved operations. In order to secure an active interest on the part of the employer it is only just that participation in the benefits of the incentive plan be accompanied by certain responsibilities, such as the assumption of losses in a sportsmanlike manner. The opportunity for gains should always be accompanied by equal provision for assuming losses and any provisions for penalties should include equal opportunities of earning a reward for good work. Plans operating successfully are usually responsible for a feeling of responsibility for conditions ordinarily considered beyond the control of the supervisor.

The proportion of a total savings paid out to supervisors is an important consideration and will usually determine whether a foreman will interest himself in a certain factor. Many plans are designed so that approximately \$1 out of every \$8 to \$10 saving is paid out in the form of premiums to the supervisors. This ratio will of course vary with the size of the department under the foreman's control. Generally speaking, the premium for a well operated department in order to be effective, should run approximately 20 to 30 per cent of his total income.

In addition to these requirements the following principles seem also to underlie an effective plan of the direct measurement type:

a. Statements should be drawn up stating definitely in advance, for what operating factors the supervisor is responsible. These statements should take into account all factors of operation and should show the standards of perfection on each factor.

b. The use of mathematical formulas and schedules in the computation of the supervisor's premium is essential in the elimination of arbitrary methods and helps to promote confidence in the justice of the plan.

c. In order to have each factor in the supervisor's incentive plan signify its proper importance, money earned on each factor for good work must be in proportion to the savings made.

d. A proper balance should be made between the number of factors used and the number of objects the supervisor should have in directing the activities under his control. Generally speaking, there should be as many factors as there are objects, but a consideration of the cost of record keeping frequently makes a deviation from this rule advisable.

e. The standards upon which savings and bonuses are to be computed should be determined from standard operating conditions. In other words, the company shall have done, through the employment of systematic and scientific management, all in their power to make the plant as efficient as they know how. Beyond this point, it can be understood that all operating improvements originating in the minds of the supervisor and showing savings on the operating statement of the department should be recognized in the incentive plan.

f. The premiums earned should be paid as often as the supervisor is paid his basic salary. This gives the employing company the maximum benefit from the operation of any incentive plan, because there is very little lag between the time of making savings and getting the bonus. The absence of this lag makes it easy to associate possible improved operating conditions with the reward that will be due on the supervisor's following pay check.

g. Incentives for the stimulation of departmental efficiency must be so designed as also to bring about harmony between departments in the advancement of general plant efficiency. When this balance in the incentive is

maintained, the supervisory organization will have the spirit, enthusiasm and self interest to operate each department and the business as a complete unit on a high plane of productive and service rendering efficiency.

Plan of the Holeproof Hosiery Company. The supervisors incentive plan used by the Holeproof Hosiery company is described in detail as an example of a direct measurement financial incentive. Its factors used as a basis for premium computation are varied, depending upon the problems existing in each department. There are some factors, however, that are universal in application to the work of all departments. These factors have been selected largely upon the principle that they are within the control of the supervisors and that they can be accurately measured. The selecting of these factors has been a process of development and has resulted from reviews of experiences in applying first one factor and then adding another. The application of one factor has frequently suggested possibilities in applying an additional factor in some other phase of operation. This development in the application of additional factors has also been dependent upon the ability of supervisors to assume responsibility for certain conditions over which they were told they had control. The factors in existence today may be summarized as follows:

1. *Productivity of Direct Workers.* This factor is a measure of the efficiency of the workers employed on standardized operations, where time standards have been established from careful time studies and motion analyses. The actual measurement of the department's efficiency on productive workers is made possible by the use of the premium wage system in operation for the productive workers as the following sample computation will illustrate:

Total basic wages of productive work of the department.	\$4,000
Total premiums earned by productive workers of department. . .	\$1,000
Average per cent premium of productive work in department. . .	25
Department's standard per cent premium.	10
Foreman's premium, average per cent in excess of department standard	15

2. *Increase in Quality of Workmanship.* Increased quality of workmanship is reflected in the percentage of perfects obtained. The foreman's premium for increases in quality is computed in combination with the premium for productive worker's efficiency shown above. This is accomplished in an automatic form by having the per cent of perfects affect the premium of the direct workers so that \$1,000 premium of the direct workers, given in the above example, is composed partly of credit for high percentage of perfects.

3. *Improvement and Training of Beginners.* The cost of training beginners is the largest factor in the tremendous cost of labor turnover. This cost can be reduced by insuring the gradual and consistent development of each beginner over a period of time until standard production is being maintained. This company has established standard beginner schedules which specify the production the beginner must turn out during each successive week of the learning period. Foremen are expected to check up all beginners with

respect to their progress in comparison to the schedules of production. These schedules vary in accordance with the skill demanded on the operations from two weeks up to as high as twenty-six weeks. The foreman is provided with an incentive to give the best training possible by eliminating from the computation of the average per cent premium of the productive workers, the records of the beginners who have attained or exceeded the beginner's schedule. The elimination of these beginners, in the computation of the department's average, has a tendency to improve this factor. While a number of beginners put in any given department may not always be within the control of the foreman, the speed with which these people improve is certainly within their control and rewards for good work of this kind should produce gratifying results.

4. *Reduction of Indirect Labor Costs.* It is our contention that all overhead costs within the control of the supervisors should enter into the computation of the supervisors' premium, if these factors are readily subject to accurate measurement. This company has found it possible thus far to measure accurately only the indirect labor costs with the hope that future developments will make possible a more accurate measure of other controllable overhead expense items in a simple and effective manner. Indirect labor costs have, however, been found subject to accurate measurement in comparison to standards. The standards for indirect labor have been established on the basis of past performance combined with a complete analysis of indirect labor requirements in the department. These standards are expressed in terms of per cent of direct labor. Savings or losses made in the expenditure of indirect labor in comparison with these standards cause either a diminution or enhancement of the total premium of the supervisors, as the following example will illustrate:

Department's total basic wages.....	\$5,000
Department's standard indirect labor at 20 per cent.....	\$1,000
Actual expenditure for indirect labor.....	\$ 900
Gain.....	\$ 100

Foreman's per cent premium on indirect labor costs	$\frac{\$100}{\$5,000} \times 5$	10
--	----------------------------------	----

You will notice in the above computation, the multiplying factor of five. This multiplying factor is used for determining premium on the basis of dollar results obtained. It is admittedly an arbitrary figure but it permits the systematic computation of a premium that will be in proportion to money value of the results achieved.

5. *Reduction of Time Work on Unstandardized Operations.* It is generally known that day work performed, while not on standard operations, is performed at about 60 per cent of possible piece work production with the operation completely standardized with regard to materials, tools, and methods. While the company has a regular staff of time study engineers, who have as part of their function the standardization of new work, the progress of standardization of new work and the facility with which standard operations are effected are dependent to a large degree upon the interest and cooperation extended by the foreman. The measurement of this item

is accomplished by including the day work wages in the computation of indirect labor costs shown in the previous factor. In other words, the department showing a gain on indirect labor of \$100 but having \$30 of wages paid in the form of time work, will have available for premium computation on the indirect labor cost factor, only \$70.

6. *Waste Reduction.* This waste-reduction factor is essentially the same as other factors. There is, however, one difference in the application of this factor in that not all supervisors participate in it. There are employed certain functionary supervisors in charge of machines, who have as their duties the adjustment of machines for proper production and elimination of waste. These people participate in this premium because they have the greatest amount of control over this item. The addition of this incentive to other workers and other supervisors not having so much control over this factor would frequently make their incentive plan confusing.
